Medical Electricity. By A. DE WATTEVILLE, M.A., M.D. London: H. K. Lewis. 1884.

NOTWITHSTANDING extensive researches and a voluminous literature, it must be confessed that the science of electricity in its relations to medicine is a subject which still remains comparatively unrecognised in this country. In other countries, especially in Germany, electricity is unhesitatingly acknowledged to be an important agent in the diagnosis and treatment of disease. Here, however, even at the present time, there is an uneasy feeling amongst the profession that there is something, as the Scotch would say, "uncanny" about the proceedings, and a lurking feeling of distrust against those who advocate its claims. A careful study of the work before us will go far towards dissipating any lingering delusions in this direction. It will indicate to the reader that, far from this being a subject easy of comprehension or capable of popular adoption, it is one of a most complicated and intricate character, and demands knowledge of the most varied and extended nature. The author, Dr. de Watteville, has for many years devoted his attention to the study of electricity in all its branches, and more especially in its relation to physiology and medical science. His labours have been conducted in the disinterested spirit of honest inquiry, and for this reason he has gained the support and confidence of his medical brethren.

The book is conveniently divided into four chapters, treating of Electro-physics, Electro-physiology, Electro-diagnosis, and Electro-therapeutics. We are glad to see that in Chapter I. the author has omitted many of the illustrations of electrical instruments, which gave the first edition too much the appearance of an illustrated catalogue. His explanation of Ohm's Law, the electrical units and density of current, is clear and concise. The importance of the use of the galvanometer, or more properly Gaiffe's modification of the galvanoscope, is thoroughly explained. The advantage to be gained by the arrangement of the elements in series or simple circuits is aptly illustrated by numerical examples. He has adopted Erb's sizes of electrodes, so that the terms fine, medium, &c., have definite meanings.

The experiments or exercises described in the chapter on Electro-physiology if repeated by the student will prove a valuable means of acquiring a knowledge of the manipulations necessary for the practice of diagnosis and treatment by electricity.

The chapter on Electro-diagnosis is a natural continuation of the preceding one, because the description of electrical reactions of normal nerve and muscle forms a suitable introduction to the study of the reactions exhibited by the same tissues in diseased conditions.

In the chapter on Electro-therapeutics, Dr. de Watteville has described the *rationale* and methods of electrisation, and he has succeeded in his endeavours to avoid excessive enthusiasm. He says "it is not so much electricity which cures as its rational and skilful application, and the often used expression 'trying electricity' conveys about as much meaning as 'trying water,' without specifying whether the water is to be hot or cold, in the shape of ice or steam, applied externally or internally, and so forth."

Dr. de Watteville censures somewhat severely those who use the term "galvanisation of the sympathetic." He considers that this "offensive expression" is founded upon "erroneous physics, imaginary physiology, and fantastic pathology." In order to remedy these evils he adopts the term subaural galvanisation. The author has also endeavoured to remedy certain "mongrel, barbarous, and ungrammatical" expressions in the nomenclature of the subject. He considers that "cathode" should be spelt with a k, and that "cathodal" should be kathodic. These changes may have some *raison d'être*, but few will care to substitute hypokinesis and hyperkinesis for paralysis and spasm.

VENTILATION OF THE HOUSE OF COMMONS.—The Select Committee appointed to investigate the causes of the offensive smells recently complained of in the House of Commons presented their report on the 30th ult. They find, after careful consideration, that the ventilation and drainage of the building are in admirable condition, but that the Westminster drain and sewer which runs from Abingdon-street to the Thames Embankment is in such a condition as to constitute a nuisance. The committee recommend that the Local Government Board should instruct one of its inspectors to examine further into the matter, and that the committee should be reappointed next session to consider the inspector's report.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SECOND ANNUAL MEETING, HELD AT BELFAST, JULY AND AUGUST, 1884.

THE meeting of the British Medical Association in Belfast, which concluded last week, will long be remembered as one of the most enjoyable gatherings of that body. The members of the Association who were present repeatedly expressed their great gratification at the cordial reception they received, not only from the profession in Belfast but from the general public; while Belfast has reason to be proud not only that a local member of the profession was in the presidential chair, but that all the details of arrangements were so well carried out by the executive committee and the numerous secretaries of the various sub-committees. In THE LANCET of last week reference was so fully made to the admirable addresses of the President, Dr. Ord, and Prof. Redfern, that we need not advert to them. On Friday, the 1st inst., the

ADDRESS IN OBSTETRIC MEDICINE

was delivered by Dr. Kidd of Dublin, who said he should ask his audience to consider Puerperal Fever, mainly from a clinical point of view, referring to the laboratory experiments of scientists and pathologists to illustrate and explain the facts observed at the bedside, where alone disease can be studied. Dr. Kidd then proceeded to consider the various forms of the disease. He described the cases due to traumatic causes. He gave an account of Burdon Sanderson's researches, and said that there were two factors for the production of the poison in these cases—(*a*) the material capable of putrefaction, and (*b*) bacteria to effect putrefaction. The material capable of putrefaction is found in the shreds of connective tissue which die in the contused and lacerated wounds of the soft parts, and this is to be obviated by conducting the labour so as to lessen the amount of injury done. The access of the bacteria to the injured parts is to be cut off by cleanliness, ventilation, and disinfection. But as the germs may also come from other parts within the body to the point where the dead or dying tissue exists, and there set up putrefaction and the elaboration of the septic poison, the indication is to remove the products of decomposition as soon as possible. He then referred to another group of cases due to the retention within the uterus of organic substances, and to a set of cases due to phlebitis. The foregoing groups belong to the class Dr. Barnes calls autogenetic; but the cases Dr. Kidd next considered—i.e., epidemics—present a different clinical history, and seem to depend on entirely different causes. In epidemics the disease may manifest itself before labour has set in. It seizes great numbers at the same time; it observes cycles of development and decline, sometimes disappearing altogether for short or long periods. At its onset it proves fatal to almost all who are attacked; as it declines it becomes more mild in its character, and many of those attacked recover. In all these respects these cases resemble diseases specific in their nature and dependent for their development on the action of a specific epidemic influence. Dr. Kidd gave an account of several epidemics observed at different periods in Dublin, and arrived at the conclusion that there is a large group of puerperal cases that come strictly within the definition of epidemic disease, and that the epidemic thus constituted is a specific disease. He showed that scarlatina and other diseases may occur in the puerperal state, but they are not samples of puerperal fever. If you sow thistles you will grow thistles, and if you sow scarlatina the crop will be scarlatina. Finally, Dr. Kidd stated very fully the septicæmic theory—i.e., that puerperal fever is nothing else but poisoning with septic matter from the genital organs; but he said that this theory seemed to him defective. He sketched the very elaborate precautions which those who held this view recommend for the prevention of this disease, but he showed that the results claimed by them as due to these precautions may not be owing to these precautions alone, for the history of great hospitals, such as Vienna or Dublin, shows that puerperal fever will prevail and cause sad mortality at times, and disappear again, and that the conditions governing its movements have not yet been discovered. From 1857 to 1860, in the lying-in hospital at Vienna the mortality was slight, though disinfectants were not used, while during the three following years, in spite of the systematic and persistent employment of those agents, the death-rate once more assumed formidable proportions. Dr. Kidd concluded his admirable address, which will, we venture to think, long remain a classical paper on puerperal fever, by saying "Let us differ as to our theories as we may, we will all unite in the earnest desire that precautions may prove not only more efficient, but more permanent in their effects."

THE SECTIONS.

On Wednesday the sections all met, and at most of them there were opening addresses by the Presidents.

MEDICINE.

In this section there was a series of very interesting discussions.

1. Dr. George Johnson introduced the subject of Albuminuria in a very exhaustive address, in which he gave a general review of the condition, its consequences, and treatment, and illustrated his remarks by a series of microscopic preparations. He also demonstrated the picric acid test. Drs. Myrtle, Hadden, Thomas, and O'Connor took part in the discussion.

2. Dr. Douglas Powell gave a very elaborate address on the Causative Relations of Phthisis, in which he argued against its contagious nature. Dr. Ward Cousins, Prof. Gairdner, and Drs. Myrtle, Barr, Green, and O'Connor spoke in the debate.

3. A discussion on Rheumatoid Arthritis, opened by a paper of Dr. Duckworth's, read by Dr. Barlow, secretary of the section, was principally remarkable for the very original address of Dr. Gordon, Professor of Surgery in Queen's College, Belfast. Dr. Gordon said he had been studying this disease for thirty years, and the numerous specimens which he exhibited showed clearly the amount of close attention he had given to the subject. He believed it had no connexion with gout or rheumatism, but when it was present there were other evidences of senile changes—viz., atheroma of the vessels and fatty heart; consequently, he considered it to be a form of senile degeneration, but it was difficult to assign its exact cause. He did not think much could be done in the way of treatment; the only remedies he used were iodide of potassium and Fowler's solution. Dr. Gordon's speech impressed those who heard it as being the outcome of most careful study and close observation, and he was frequently applauded during its delivery.

SURGERY.

The opening address of the President (Sir William Mac Cormac) has already been referred to in these columns. There was a very instructive discussion on the treatment of Spinal Curvature, introduced by Prof. Sayre. A number of members followed with interesting remarks, some disagreeing with portions of Dr. Sayre's paper, while others concurred. Mr. Roth, Mr. Keetly, and other gentlemen spoke.

Among the papers read in this section we may mention that of Mr. Makins on Successful Suture of Small Intestine in a case of Fæcal Fistula; the Radical Cure of Hernia by Torsion of the Sac, by Mr. Ball; the Surgical Treatment of Hydatid Cyst of the Liver, by Mr. R. Richardson; and a paper on the Nature of Rifle-Bullet Wounds and the Principles of their Early Treatment, by Dr. Kirkes. Mr. Fagan gave a demonstration of his transport splint in the College grounds.

OBSTETRIC MEDICINE.

In this section, the President, Dr. Clement Godson, who used every exertion to make his department of the meeting a success, gave a very interesting opening address on the Surgical Aspect of Obstetrics and Gynæcology. He showed that it was impossible to practise either of these branches of medicine without "dabbling in surgery," and that it was absurd to argue that an accoucheur should be a physician pure and simple. He explained that a rule forbidding the obstetric physician to perform surgical operations existed in certain of the large London hospitals, and that, as a consequence, the obstetric staff were driven to seek appointments to special hospitals for the treatment of diseases of women to gain experience to enable them to teach in their schools.

A discussion on the Pathology and Treatment of Extra-uterine Fœtation was introduced by Mr. Lawson Tait, who came specially to Belfast for this purpose. A number of members spoke.

Dr. Atthill opened a discussion on the Treatment of

Digitized by Google

Intra-uterine Disease, with special reference to the best mode of making appliances for the intra-uterine surface. Dr. Atthill's masterly paper was chiefly remarkable for recommending the injection of iodised phenol into the uterus in the treatment of suitable cases. Papers on the same subject were also contributed by Dr. More Madden and Dr. John W. Byers; and in the discussion which ensued Drs. Kidd, Smyly, and Reid took part.

In this section the President demonstrated the plan of using his four-bladed perforator, and Dr. Kidd showed his method of decapitating the child. Several other interesting papers were read.

PUBLIC MEDICINE.

In this section, the only one to which the public were admitted, there was a great deal of work done.

The President, Dr. Cameron, M.P., delivered a very able, exhaustive, and thoughtful address on the Cholera Microbe, and how to meet it. Papers were read by Dr. Johnston on the Prevention of Epidemics, by Dr. Cullimore on Quarantine, and by Dr. Hunt (New York) on Infectious Diseases. Dr. Kirkes read a very interesting paper on the Visit of the Egyptian Cholera Epidemic of 1883 to Port Said. Prof. Charles A. Cameron (Dublin) read a paper on Inspection of Meat Markets, which excited considerable interest. The discussion on Over-pressure in Schools was closed by the President, who remarked that something might be done by legislation to prevent the evils complained of, not by cutting down education, but by placing education on somewhat more rational lines.

PHARMACOLOGY AND THERAPEUTICS.

Dr. Maclagan, the President of this newly formed section, delivered an opening address on Methods of Therapeutic Research, after which there was an interesting discussion on the British Pharmacopœia, in which Dr. Shoemaker gave an account of the state of the Pharmacopœia in America. A resolution was passed calling for an improvement and revision of the present Pharmacopœia.

The Patent Medicines Stamp Act was brought under the notice of the section by the President, and eventually the following motion, proposed by Professor Hay (Aberdeen), and seconded by Dr. Leech, was unanimously carried:—"That in the opinion of this section the Patent Medicines Stamp Act should be abolished."

Dr. Shoemaker (Philadelphia), a delegate from the American Medical Association, gave a demonstration on New Oleates; and in the discussion which followed Dr. Finny and Dr. Walter Smith of Dublin took part. There was also a debate on Antipyretics, introduced by Dr. Collie (Homerton Fever Hospital), who dwelt on Cold Baths. Dr. Quinlan followed, speaking in reference to salicin, salicylates, quinine, and kairin. Dr. Ord and Prof. Gairdner also took part in this interesting and animated debate. There was finally a debate on Aspiration as a therapeutic agent; and a demonstration of the action of certain drugs on the frog's heart. There can be no doubt that this new section was a marked success.

PHYSIOLOGY AND PATHOLOGY.

In this section Dr. M'Vail read a very able paper on the Pathology of Pulmonary Emphysema, which was criticised by Professor Gairdner and others.

Dr. Alexander (Liverpool) gave a very scholarly address in opening the discussion on the Influence of the Nervous System on Normal and Abnormal Nutrition. Numerous papers were read in this section.

OPHTHALMOLOGY.

After the President had given his opening address on Mature Cataract and its Treatment by a new Operation,

Dr. Wolfe opened a discussion on the following question:—"Does the position of the section in Cataract operations influence Suppuration of the Cornea? If so, what part is played by Septic Infection?"

Dr. Brailey opened a discussion on the Explanation of the Advance of the Iris Periphery in the late stages of Glaucoma. A number of papers were read, and other discussions took place in this section.

PSYCHOLOGY.

Among other matters of interest in this section, Dr. Hack Tuke read a paper on Alcoholic Beverages in British Asylums, in which he narrated the result of an inquiry into the use of alcohol in asylums. Several superintendents approved of beer, while many did not. Alcohol was used as a medicine only in 22 asylums in England, in 13 in Scotland, and in 15 in Ireland—50 in all. Dr. Norman Kerr said that nearly one half of the English asylums had either wholly or partially discontinued the use of alcohol; there were 63 such institutions in all, and there had been either an entire or partial reduction in 29.

THE ANNUAL MUSEUM.

The annual museum, owing to the great exertions of Dr. O'Neill, was a decided success. The purely medical and surgical exhibits were shown in the anatomical rooms, while in the gymnasium and exhibition hall of the gardens appliances relating to sanitary science and public health were to be seen. The show of drugs and instruments was very extensive, Arnold and Sons, Coxeter, Weiss, Marr, Mayer and Meltzer, Wilson and Sons (Harrogate), Allen and Hanburys, Burroughs, Wellcome and Co., Calvert, Corbyn, Stacey and Co., Essinger and Neuberger, Sanitas Co., &c., being among the exhibitors. There was some very good hospital furniture, and filters, tricycles, a doctor's gig, carriage, &c. Dr. Clement Godson exhibited a thermostatic nurse for the bringing up of prematurely born infants, an account of which appeared recently in our columns. This apparatus excited great curiosity, and its mechanism was frequently explained by Dr. Godson to visitors to the museum.

LAST GENERAL MEETING.

At this meeting, after the adoption of various reports, special votes of thanks were passed to the President of Queen's College for allowing the use of the College for the meetings; to the Mayor; to the members of the Belfast and North of Ireland Branch, and the inhabitants of the town and neighbourhood; to the National Telephonic Company; to the honorary secretaries and others who had assisted in the entertainment of the members; and, lastly, to Dr. Cuming, the President of the Association.

The annual dinner was held in the Examination Hall of Queen's College, Professor Cuming presiding, on Thursday evening, July 31st; while on the Friday night the Mayor of Belfast, Sir David Taylor, gave a very brilliant reception in the Ulster Hall, at which there was a very numerous attendance. Dancing was commenced at half-past ten, and was continued into the early hours of Saturday.

On Saturday, which was a beautiful day, there were three excursions—one to the Giant's Causeway (at which there were between two and three hundred), another to Garun Tower, and a third to Newcastle.

The numerous social reunions have been a marked feature of the Belfast meeting. There were garden parties, "at homes," and other entertainments, to which the members of the Association and their friends were freely admitted.

"THE WASTE OF THE PROFESSION."

To the Editor of THE LANCET.

SIR,—Without attempting to guess what the average annual waste of the profession may be, permit me to point out a waste that has not been referred to either by Sir Lyon Playfair or by you. I mean the large loss caused by the retirement of medical men from active practice on account of age, ill-health, or other causes, and whose names would not of course figure in the annual return of deaths. I have no idea what this waste is, but no doubt it is considerable. Perhaps some of your correspondents could enlighten me; for so far as the public are concerned, it is a very important matter to know.—I am, Sir, yours, &c.,

T. F. O'DWYER, M.D.,
Surgeon-Major, Army Medical Department.

Junior United Service Club, August, 1884.

*** We quite agree with our correspondent that the mere deaths do not express the whole loss of active members of the profession in any year; but it requires little knowledge of either the circumstances or the disposition of medical men to be convinced that the number who retire is a comparatively small one.—ED. L.

THE Local Government Board for Ireland have sanctioned an increase in the salary of Dr. Agnew, of Lurgan Dispensary, by £20 yearly.

THE LANCET.

LONDON: SATURDAY, AUGUST 9, 1884.

THE meeting at Berlin, on the 26th ult., of many of the leaders of our profession, including such men as Professors VIRCHOW and HIRSCH, to discuss the subject of cholera, and to listen to the history of his work by Dr. KOCH, is an occasion of more than passing interest. The conference and the masterly address with which it opened may almost be said to mark an epoch in the history of this disease. At a time when all Europe is alive to the subject, and when fears of a general epidemic are aroused, the demonstration of what promises to be a very fruitful discovery comes most opportunely. Without entertaining too sanguine a view, it is surely something to know that the methods of rigid investigation that have been so successfully applied to elucidate the nature of infective disease have been carried out so far with equal success in the case of cholera. It brings forcibly to mind the manner in which, from henceforth, all such diseases must be studied; their intimate nature must be made clear to us before we can hope to cope with their ravages. In the portion of his address yet published, the substance of which will be found elsewhere, Dr. KOCH has not approached the subject of the practical application of the gains to knowledge he has obtained. All will concur with his opening statement that without a sound basis of the knowledge of the essential nature of cholera all therapeutic and prophylactic efforts are vain—a truism too often disregarded even in these enlightened days! The work, in which KOCH himself has been one of the pioneers, that signalises the past decade has yet to bear its legitimate fruit in a rational treatment and a systematised attack against the conditions that favour the origin and spread of infective diseases; and the time will surely come when we shall no longer be content with enforcing the principles of sanitation, useful and fruitful as that labour is, but shall be possessed of measures aimed more directly against the causes of these diseases. To be sure, there are many who doubt the significance of the micro-organisms which appear to constitute the virus of so many of these diseases, and who believe that the parasitic theory is being pushed too far, blinding us to the broader features of epidemic influences. But evidence in support of that doctrine accumulates on all sides and grows stronger day by day. Mistakes, even grave errors, will often be made from lack of sufficient care in observation and experiment or from too hasty generalisation, but the main principle remains unshaken, the principle of zymosis.

Cholera is admittedly a zymotic disease, and the search after its organic germ or parasite has been carried on for more than forty years. Amongst the numerous alleged discoveries, HIRSCH mentions the "cryptogamic bodies, like ferment fungi," found by BOHM in the dejecta and intestines (1838); the "annular bodies" detected by BRITTAN and SWAYNE in the Bristol epidemic of 1849, an observation in part confirmed by HUGHES BENNETT of Edinburgh; the "vibrioes" of POUCHET; the "cercomonas" of DAVAINE; and the "small granular bodies composed of round cells resembling the bacterium termo," discovered by PACCINI in 1854 and 1856—an observation which, like that made by Dr. BRISTOWE and referred to in his letter we published last week, most harmonises with the present discovery of KOCH. HIRSCH also refers to the observation of M'CARTHY and and DOVE, of "large masses of cellular elements endowed with active power of movement," and the memorable researches of HALLIER, KLOB, and THOMÉ, with their refutation by DE BARY and COHN, and the equally inconclusive results obtained by CUNINGHAM and LEWIS. The importance of KOCH'S discovery is heightened by these previous attempts, and the great merit of his work is the fact that he has succeeded in differentiating from among all the numerous species of bacterial life that infest the intestinal canal one characteristic and constant form. He has been enabled to present the world with so consistent an account of the life-history of this cholera microbe as to overcome the scepticism born of previous failures. He has succeeded because he has adopted the methods above referred to—methods the value of which has not hitherto been properly appreciated in the country where cholera is indigenous. The despatch by our Government to India of two scientists well versed in these methods will serve to redeem us from that reproach.

In following Dr. KOCH'S remarks one is struck by the fact that in the majority of the cases examined by him he found evidence of severe inflammatory lesions of the intestinal mucous membrane, often with hæmorrhage; and he notes the rarity with which the intestinal contents are of the watery character so marked in the evacuations earlier in the disease. By the light of his microscopical investigations, it is not surprising that the intestines should suffer such severe lesions, although the general experience hitherto has been to the contrary; for he found accumulated within the tubular glands, and beneath the epithelium, an abundance of bacilli, to which were superadded many putrefactive bacteria. However, he succeeded in isolating the bacillus, and found it in the recent stools of acute cases, and in the linen soiled by choleraic dejecta. Its characters appear distinctive; shaped like a comma, and smaller in size than the tubercle bacillus, it grows with great luxuriance, and assumes the form of a spirillum. Indeed, Dr. KOCH appears more inclined now to regard the micro-organism as belonging to the genus spirillum rather than to that of bacillus, not only on these morphological grounds, but on the facts of its life-conditions. He always speaks of it as the "comma bacillus" (he seems careful not to use the term "cholera bacillus"), and that name expresses its most constant and obvious feature. The microbe has not been found in the blood or viscera other than the intestine; a fact not only explicable of the symptoms of cholera, but of its mode of propagation by means of ingesta.

Interesting as the discovery of a special organic form is, it is far more important to know the conditions that favour or prevent its development; and this part of the subject has been very fully gone into by KOCH. It will be seen that in many respects the comma bacillus differs from other bacteria. Thus it grows and multiplies in appropriate media with remarkable rapidity, and the characters of the colonies thus formed are different from those usually observed; whilst its

Digitized by Google

behaviour in a gelatine medium is, so far as known, quite characteristic. It resists a considerable degree of cold; and although its vitality is affected by the withdrawal of air or oxygen, or the subjection to an atmosphere of carbonic acid, it appears to be not actually killed, but only rendered dormant. What, however, is of the first importance is the discovery that the comma bacillus cannot exist apart from moisture. Many bacilli when subjected to dryness still retain vitality, which is shown by replacing them in a moist nutrient medium; but this comma bacillus is actually killed outright by such exposure. It is needless to point out the practical bearing of this in the disinfection of linen soiled by the dejecta. Instead of placing such in so-called disinfecting fluids, it is enough to subject them to dry heat, for twenty-four hours at the longest. Dr. KOCH seems rather to deprecate the use of so-called disinfectants, which operate in destroying the putrefactive bacteria, but leave the comma bacillus free to luxuriate. For his observations have led him to the conclusion that the existence of putrefaction is just the condition that is most likely to arrest the growth of the specific bacillus, an observation full of suggestiveness. It would seem as if the actively growing and multiplying comma bacillus, which finds its lodgment in the intestinal mucosa, sets up those changes which prepare the way for the bacterial invasion that supplants the former. The soil is prepared for the putrefactive organisms, and the non-pathogenic bacteria enter into a struggle for existence with the pathogenic bacillus, and overcome it. If this be true, a considerable revolution will have to be made in preconceived ideas, and putrefaction will come to be regarded as opposed, and not as favourable, to the spread of cholera! We would not desire as yet to generalise so freely as this, but await with interest the further development of the problem by Dr. KOCH. His statements as to the amount of the various antiseptic agents requisite to check the development of the comma bacillus give ground for the assertion that the internal administration of such substances in cholera is beyond the reach of practical therapeutics. The amount of any of those agents that could be safely given would be far below that which could possibly act upon the luxuriant growth of the bacillus in the intestine. Such is the deduction from his research; and in its bare reasonableness it seems to overturn a host of vaunted specifics and modes of treatment, based, indeed, on the zymotic theory, but without a due appreciation of what that theory involves. It once more demonstrates that in prevention lies the main line of attack against cholera; the cure of the disease depends less upon any specific medicament than upon measures adopted to check the violence of the disease and to maintain the vital powers under its terribly exhausting effects.

WE propose to discuss briefly the important subject of reflex paralysis, on which an able paper has recently been read by Dr. NIXON before the Academy of Medicine in Ireland. As the matter is one about which volumes might be written, we think it would conduce to a better understanding of the various elements of the subject if we presented to our readers an exhaustive account—exhaustive not in the sense of abundant illustration by cases or in the employment of periphrasis, but complete so far as enumeration and exposition go of the chief views which may possibly be held with regard to reflex paralysis. It is first of all expedient to define what is meant by reflex paralysis. There would be no necessity to write this article on the subject if a perfect definition were possible, so that the reason of the lameness of the following definition may be at once apparent:—Reflex paralysis may be said to be a loss of motion or sensation in parts of the body physiologically remote from a disturbance produced by injury or disease of tissues supplied with nerves. As alleged instances of the occurrence of reflex paralysis, the following may be mentioned: amaurosis after affections of the fifth nerve; paralysis of orbital nerves following severe neuralgia of the trigeminus; paralysis of the third nerve after injury of the supra- or infra-orbital nerves; amaurosis coming on after irritation of the dental nerves; paralysis following wounds; and lastly, "reflex" paraplegia from diseases of the urinary organs, dysentery, and certain affections of the uterus. Let us take the case of paraplegia following on disease of some of the abdominal viscera and examine this combination of phenomena from every possible point of view. In doing this we think it advisable to say that we purposely avoid any typical instance of the phenomena in question, partly because we do not wish to be fettered by any subordinate considerations, and partly because we would indulge in as wide and full an examination as possible.

There can be but little doubt that in the majority of cases the paraplegia is due to an affection of the central nervous structures of the lumbar region of the spinal cord; the bilateral character of the palsy supports this view; and it is hardly likely that the nerve-trunks in their passage downwards and outwards could be equally affected. Admitting these considerations, the question arises as to how the lumbar region of the spinal cord gets damaged. The result may be brought about by the intervention of the process termed "inhibition." The simplest example we possess of this phenomenon may be inferred from an experiment on a headless frog. A bit of blotting-paper, moistened with acetic acid, placed on the inner aspect of the thigh, is soon followed by movements apparently directed to the removal of the offending paper. If whilst these movements are in progress one of the feet be tightly clamped the reflex action is done away with, is "inhibited." Here it would seem that a powerful afferent stimulus is directly able to arrest a nervous action; but we must be careful in drawing even this inference, for other explanations are possible. It may be that the stimulus acts by causing spasm of the vessels supplying some part of the reflex centres in question. So far we have been dealing with states of tissues which may be termed "functional."

The paraplegia, or rather myelitis, may be due to disease spreading along the nerves by means of mere continuity of tissue or by way of special lymphatics or bloodvessels—respectively an ascending neuritis, lymphangitis, or phlebitis. We forbear to increase the complexity of this group by further subdivision.

Again, it is conceivable that the abdominal mischief and paraplegia are merely coincident, or related only in the same way as a parent is to two children. If we may speak of genuine reflex paralysis, that term ought only to be employed to designate the loss of function which ensues when the

Digitized by Google

agency at a distance acts without producing any demonstrably structural lesion. Sir WILLIAM GULL and others have shown that myelitis and consequent paraplegia may be set up from disease of the urinary organs, apparently as the direct result of propagation of inflammatory action either along the nerve trunks or venous channels. LEYDEN has corroborated these views by demonstrating the existence of ascending neuritis in some of these cases of paraplegia. It is still a moot point whether a continuous line of inflammation along the nerve trunks is necessary for the development of myelitis. TIESLER, FEINBERG, and HAYEM found that the application of various irritants to the sciatic nerves of animals was followed by paraplegia. Suppuration existed at the site of irritation of the nerve and another abscess was discovered also at the origin of the nerve from the spinal cord; the length of nerve intervening between the foci of purulent infiltration being apparently healthy. REMAK and KUSSMAUL thought from their observations that a chronic inflammation of the nerves in the pelvis might be produced by a phlegmon in this region without any myelitis—in fact, a simple descending neuritis. The central nervous apparatus of the lumbar region may be functionally ruined by the absorption of poisons locally produced, and acting as some of the alkaloids are supposed to do, proper nutrition being impossible in the presence of altered blood. The nerve-cells may be placed *hors de combat* not only by inhibition, but also by sheer exhaustion. To use a simile, we may imagine a jug full of water, with a tightly-fitting lid, to represent a loaded nerve-cell; the "vis nervosa" therein contained may be wasted or rendered of no use by completely emptying the jug (exhaustion) or by tightly closing the lid (inhibition). Proceeding further, it is easy to understand how these states of inaction may be brought about by many means; whether these means be from structural or functional defects influencing the nutrition of the nerve-cells, it is plain that every cause must act in one of the two ways, though the degree of exhaustion or inhibition may vary considerably.

THE attention attracted to the sanitary surroundings of the schoolboy of the present day, from the elementary board schools through all grades to the higher public schools of the country, has been quickened by the important Conference which met at the International Health Exhibition on the 30th ult., as well as by the first meeting of a new Association of Medical Officers of Schools held a few days previously, a report of which appears in our columns of August 2nd. To the important bearing of this subject we have been fully alive for many years past, as the contributions in our columns testify. In THE LANCET of Jan. 21st, 1871, the following words occur, "Both at the point of departure and the point of arrival a clean bill of health should be found for the schoolboy." At each of the meetings referred to prominence was given to the necessity for parents to be perfectly candid with the heads of schools on their boys' return from any infected locality; but we fail to see that equal prominence was given to the still greater necessity for heads of schools to be equally candid when their pupils return home during the existence of any infectious malady in their school. There would appear to be some risk that the new Association of Medical Officers of Schools, in their interest to protect their individual institutions, may exact undue restrictions on the pupils' return, and fail to see that parents and the public at large have an equal right to protection from the risks of infectious maladies, engendered or contracted among pupils at school at the approach of vacation time, being spread to their homes. Already we see danger of this; hence the prominence we desire to give to it. The authorities of every school should be required to state candidly to parents whenever an infectious malady arises in their establishment; and if it should exist on the approach of vacation time, the term should be extended beyond the period of possible incubation of the disease among the pupils generally, for the protection both of their families and of the public. How can such protection be best ensured? In the first instance, parents should make it a condition on sending their boys to any school that they be informed of the occurrence of any infectious malady among the pupils, and especially so on the approach of vacation time. This should not be with a view of removing boys from the infected area, but in order to cut off, as far as may be thought desirable, communications with home and regions outside the infected locality. We fully foresee the inconvenience this may occasionally give rise to in obliging school authorities to defer vacations for a brief period when infectious illness exists among the pupils; but we hold that schools should be made no exception to the accepted rule of civilised life, that the few must submit to occasional inconvenience for the sake of the welfare of the many.

In the communication made by the resident medical officer of Christ's Hospital, Mr. ALDER SMITH, at the Health Conference, it is stated that "the most important precaution to prevent infectious disease from entering and spreading in a school is undivided medical responsibility." In this sentence we think we detect a trace of dissatisfaction at the exercise of superior authority by the head master and house masters of our public schools over the medical officer, limiting the exercise of his free judgment, and often curtailing his usefulness. That the responsibility on matters of illness and hygiene should be strictly medical there can be no doubt; but we believe there is room, nay, a growing necessity, for that most useful division which would be afforded by the appointment at all our schools of one or more medical officers to attend the sick, and a public sanitary medical officer for the protection of the school and the district around. Such a system works well at Eton, Winchester, and Rugby. At Eton any of the local practitioners are called in by the house masters at their own choice; at Winchester two medical officers are appointed; while at Rugby one is in sole charge. Yet no inconvenience that we have ever heard of has arisen from this dual and triad attendance; on the contrary, we think that occasional consultations must be beneficial at schools as in private life. Over each of these establishments the sanitary authority of the district has jurisdiction, with their sanitary medical officer as adviser, for the good both of the school and the contiguous district. We believe there will be provided in due course a much more minute supervision of our public schools by an officer of health absolutely independent of and free from the authority of head master, of house masters, and the governing authority of schools, whatever it may be;

Digitized by Google

an officer responsible to the local sanitary authority and through that authority to the Local Government Board. At no very distant time no building will be permitted to be occupied for school purposes, either private or public, which has not been inspected and approved by a public sanitary authority. We believe even more than this to be desirable in the interest of the schoolboy, and that there should be special and periodical inspections of all our schools, public and private, by officers of the sanitary department of the Local Government Board for all those functions in hygiene which are fast passing out of the sphere of the medical attendant on the sick.

DR. CULLINGWORTH, of Owens College, Manchester, calls attention to the evidence of epilepsy and the reasonable presumption of insanity in the case of JOSEPH JAMES DONNELLY, who had been sentenced to death for the murder of his sister and for severely wounding his mother, in a paroxysm of what may have been epileptic furor, and who has since been respited during Her Majesty's pleasure. We confess that it is always with suspicion we view the plea of insanity when propounded with the purpose of preventing the execution of a capital sentence. We think matters of this sort should be dealt with *finally* at the time of trial, or rather before it. After sentence has been pronounced there is so much motive for straining points in favour of a condemned murderer that a calm judgment is almost impossible. Nor do we think it expedient, in the interests of public safety, that there should be this last chance of escape open to criminals. At the same time it cannot be denied that there are instances in which there is need of revision of the decision at which a jury has arrived, and we are inclined to think this is a case in which inquiry was justified. There are, nevertheless, features in the case of DONNELLY that do not readily lend themselves to the presumption of his insanity. For example, while it is true, as pointed out by Dr. CULLINGWORTH, that the sister and mother attacked were not at the time so obnoxious to him as was his father, it cannot be forgotten that the sister had just refused to get him some water to drink, and, for the moment at least, she may therefore have been the object of his special animosity. It is necessary to bear in mind that in the most clearly marked cases of epileptic mania, there is generally an entire absence of motive or cause of quarrel! The maniac without preparation instantly attacks the nearest person, though he be his dearest friend.

There is, of course, a well-known class of cases in which the epileptic is simply irritable and quarrelsome, and liable to be strongly excited by the slightest provocation; but with regard to the irresponsibility of a person excited, even though there be disease at the bottom of his irritability, we are more than doubtful. We do not think the ill-temper and excitability caused by disease should be accepted as excuses for wrong-doing, or for that recklessness which leads a man to give way to his passion regardless of consequences. If the irascibility of epilepsy were to be regarded as a plea of excuse, we see no reason why the irascibility which is often caused by gout, or that peevishness characteristic of one stage and form of phthisis, and that which accompanies certain of the physiological processes and changes in life, should not also be so regarded. Science knows nothing of sentiment; and we cannot consent to strain points for the sake of what is called humanity. There is, doubtless, great need that the law should be amended in regard to the definition and determination of legal insanity; but we are of opinion that it is also desirable that an attempt should be made to arrive at a better and clearer understanding among ourselves on this subject. Too much is left to individual judgment in the matter, and individual judgment is always likely to be influenced by feeling. Again, medical men range themselves on either side of a suit or cause in which "insanity" is alleged and denied, as lawyers range themselves, but the lawyers at the bar are confronted by lawyers on the bench, who can check the ardour of professional partisanship. It is not so with the profession to which we belong. Unfortunately, there are no medical authorities in high places to whom justice can appeal for an impartial summing up of medical evidence or the just estimate of medical opinions. Medical men as experts cannot be regarded as witnesses to facts. So long as the law persists in so regarding them, there must needs be confusion and uncertainty. It is never a fact of which a legal tribunal can take cognisance—that any accused person is or is not insane. The sanity or insanity of any individual must always be a matter of opinion, and the evidence given by a medical man is an expression of that opinion. The best lawyer in the country is only an amateur, *qud* lawyer, when he attempts to pronounce judgment on the value of a medical opinion. He cannot possibly know anything about it. If he attempts to value the opinion before him he must either do so on the ground of the qualifications or the repute of the medical witness, or he must go outside the opinion given in evidence, and, forming an independent opinion of his own—necessarily a lay opinion—accept that which most closely coincides with the view he has formed. We are simply stating facts. We repeat that the sanity or insanity of no person can be a *fact;* it is a condition, not a quality, and therefore a matter of opinion, and all medical evidence is an expression of opinion. This being so, it is manifestly of the highest moment to determine among ourselves on what grounds and in what way our opinions are to be formed. Let us not wait for the reform of the laws which all desire, but simply settle this preliminary matter and make known the decision at which we have arrived. Such a procedure will not simply help the cause of justice, but tend to place our profession in the position it ought, sometimes at least, to occupy—namely, that of leading instead of following, as is too much our fashion, albeit we are not content.

A MELANCHOLY case of death from the drinking of carbolic acid, in mistake for beer, by a workman engaged in repairing drains at Forest-hill, indicates very strongly the need for greater precautions being taken by the local authorities in their method of supplying powerful disinfectants. The element of danger attending the supply of such agents with a free hand should be practically recognised by those charged with the important duty of distributing them.

AT the conference convened by the Medical Society and the National Health Society, the subject for discussion on the 1st inst. was Recreations and Gymnastics. After the reading of several papers, Sir James Paget maintained that the English system of gymnastics—namely, out-door games—was far superior to the German, Swedish, or any other system.

"Ne quid nimis."

THE COLLEGE OF PHYSICIANS AND CHOLERA.

THE College of Physicians, thinking that the public in England may fairly look to them for advice and guidance, have issued instructions. They, above all things, recommend sanitary measures, pure water, free ventilation, avoidance of overcrowding, great cleanliness, and thorough drainage. They point out the danger of excess in eating and drinking. Milk and also drinking water should be boiled; vessels used for food should be cleansed with boiling water. Persons engaged about cholera patients are not, *with proper precautions*, more liable to the disease. Of these precautions extreme cleanliness and the use of disinfectants, such as carbolic acid, are the principal. House-to-house visitation should be organised and temporary hospitals established. These hospitals should be numerous rather than large. Any unusual looseness of the bowels ought to be promptly attended to. Medical advice should be sought, and meanwhile ordinary medicines, such as chalk mixture and cinnamon powder, may be taken. These instructions are perhaps mild and trite, but they are sensible; and, as the most of them apply to other diseases as well as cholera, they cannot be accepted too gratefully by the public.

SANITARY CONDITION OF CALCUTTA.

THE sanitary condition of Calcutta continues in a very unsatisfactory state. Cholera and small-pox are spreading, and in April the death-rate of the city had risen to 50·3 per 1000 of the population. The municipal commissioners have declined to accept the offer, made to them by the Lieutenant-Governor, of a reduction of about one and a quarter lacs of rupees in the police tax on condition that the municipality should expend annually a lac on sanitary works and improvements in addition to the sum already devoted to that purpose. This decision has roused the European residents to action, and a memorial is to be presented to the Lieutenant-Governor, urging him to appoint a special "commission, under Section 28 of the Municipal Act, with the object of furnishing the Government with a substantial report on the broad question of sanitary and structural reform in the city." It appears to us to be imperative on the Government to take some prompt and efficient measures to overcome the apathy and selfish delay of the commissioners. When the lives of so many are endangered by the disgraceful state of the "bustees," it is clearly impossible to allow the interests of house-owners to interfere with measures of public sanitation. Mr. Justice Cunningham, in a letter published in the *Englishman*, says: "The ravages of disease and death in the miserable localities are chronic, constant, and enormous, and the needless misery and loss of life thus wantonly and persistently inflicted on the poor and unprotected portion of the inhabitants is a crime of which we ought to purge our consciences without delay." Surgeon-General Payne, in a letter to Mr. Cunningham, points out, in our opinion correctly, as one of the chief causes of this unsatisfactory state of things, "that there is no sanitary administration in Calcutta, where there is a large administrative body whose most important duty is the protection of the public health, and all sorts of municipal committees. Where there are numbers there can be no sense of responsibility, which alone is fatal to administration." Dr. Payne suggests that an independent committee should be appointed to study the wants of Calcutta, and steps taken to secure that their plans be carried out. "No good can come of general admonitions, or of lecturing seventy-two men on responsibility which human nature does not permit any individual among them to feel; or of accepting budget allotments as a guarantee for good work, with no critic to tell us whether the money is devoted to the work of the greatest urgency." He at the same time points out how much may be done, and ought to be done, in the way of self-help, especially in enforcing vaccination and revaccination among servants and *employés* in large establishments. "If every head of a house, or an office, or a firm in Calcutta were to declare that after a given day no person should enter his premises who had not been vaccinated within a certain period, there would be better protection in a month than any number of memorials can confer, and the Corporation would derive more help in their work than any order or sanction of Government can give them." We trust that the Lieutenant-Governor may see his way to adopt such measures as shall prove adequate to enforce the prompt action requisite in the interests of the public, and to entrust the charge of the sanitary arrangements of Calcutta to a small but efficient body of experts, armed with powers to carry out such improvements as they may deem necessary to ensure the health of the general population.

THE ADDRESS IN THE OPHTHALMOLOGICAL SECTION AT BELFAST.

DR. MCKEOWN occupied the greater part of his address to the ophthalmologists who have congregated at Belfast with an account of his method of treating and operating on cataracts. This method consists in the injection of water into the capsule of the lens at a temperature at or about that of the body. He justly remarks that in any new operative procedure the most minute particulars are of consequence—and in the present case these details are wanting,—but so far as we are able to judge from the account of his address, he appears to recommend the extraction of the lens in all cases of cataract, whether mature or immature, and that he trusts to the removal of the cortical substance, which is so often a cause of secondary cataract, by means of the intra-capsular injection of water. The plan is feasible enough, but we would suggest the employment of what is termed by the histologists normal solution—i.e., a 0·75 per cent. solution of common salt—rather than pure water. He thinks that by this means all cortical substances may, with care, be washed away; but in the report of his speech some remarks are made which are at present difficult to understand, and require elucidation. Thus he speaks of the introduction within the capsule of a needle attached to an ordinary hypodermic syringe, and remarks that "if there be any part of the lens substance easily disturbed, the injection usually ruptures the capsule a little at the point of puncture, and washes out a good deal of cortex." Is Dr. McKeown speaking of an ordinary extraction? If so, we should think the lens substance was considerably disturbed. If not, does Dr. McKeown inject water into the globe without any escape being possible for the excess, and under these circumstances, how much can he inject? Is not this a dangerous proceeding?

INTESTINAL SEPTICÆMIA.

THE possibility of septicæmia occurring as the result of absorption of putrid material developed in the intestine has been the subject of inquiry by Gaspard, Stich, Piorry, and others. A case of some interest has been narrated in detail by MM. Lépine and Mollière in No. 29 of the *Lyon Médical*. The patient, a man aged forty-four, was first under the care of the latter gentleman for a strangulated gangrenous hernia of the right inguinal region. It was deemed advisable to make an artificial anus, and it turned out that this unnatural opening led into the ascending colon, and not into the small intestine. All was going on well for

Digitized by Google

months, when one day, without any obvious cause, the patient became delirious, a scarlatiniform rash appeared on the whole surface of the body, the pulse increased in frequency, the pupils became greatly dilated, but there was no pyrexia. On account of the appearance of these symptoms the patient was transferred to the medical care of M. Lépine. The fauces were not inflamed, though the throat was said by the patient to be dry, but no lymphatic enlargement could be detected. The rash did not disappear. The symptoms could not be laid to the charge of belladonna or any other medicament, for the patient had not taken any drug whatever. Zuelzer and Sonneschein have extracted from putrid liquids a ptomaine giving rise to all the toxic properties of atropine; and M. Lépine, bearing this and the condition of the intestine in mind, diagnosed "auto-intoxication par une ptomaine atropique." This hypothesis fully explained the strongly dilated pupils and scarlatiniform rash and other symptoms, as well as an intense conjunctivitis which appeared later on, as did also an irregular pyrexia. The man died of asthenia. The necropsy revealed a horrible state of the large intestine beyond the artificial anus. The colon contained a putty-like mass, extremely fetid, and it is said of an odour *sui generis*. It seemed that the washings of the bowels, which had repeatedly been made, were totally inefficacious.

CHOLERA AND CREMATION.

AMONG the objections to cremation the risk of practising it on bodies not really but apparently dead has often been urged, particularly in Southern Europe, where, except in special cases, burial follows so rapidly on the certified cessation of life. This objection has just been revived with some force, coincidently with the recall of public attention to Pacini's remarkable paper on "Morte apparente, l'ultimo Stadio del Colera Asiatico" (apparent death, the last stage of Asiatic cholera). There are, according to the Tuscan pathologist, four stages in the course of this malady:—1. The premonitory stage, in which the intestinal transudation produces diarrhœa or, instead, gives rise to intestinal borborygmi from the reabsorption of the liquid transuded. 2. The hydrorrhagic stage, in which the intestinal transudation, becoming excessive, begins to cause diminution of the aqueous part of the blood and of the tissues, producing, when this is not retained in the intestine, the dejections properly so called. 3. The algid or asphyxial stage, in which, the aqueous part of the blood diminishing more and more, followed by diminution of the circulatory movement and all the other functions depending on it, the intestinal transudation also diminishes and the dejections cease. 4. Stage of apparent death, in which the intestinal transudation is on the point of ceasing, with the circulation of the blood and with life. In this last stage the circulation has not really ceased, as it usually does in ordinary cases of syncope and asphyxia, but is only reduced to extreme slowness; as a proof of which may be cited the fact that in cholera patients assumed to be dead ("nei pretesi cadaveri dei colerosi"), very often not only the temperature rises, but even the cyanosis disappears on the sanguineous stasis of the cutaneous capillaries resolving itself. The pathological induction by which Pacini arrives at his thesis, and the therapeutic doctrine he bases on it, would be more in place in another annotation; at present it will suffice to indicate the cases of apparent death he adduces, and the admonition it conveys to the advocates of immediate burial or immediate cremation. Prof. Betti, in the cholera epidemic which ravaged Florence in 1854, recorded several cases of marked rise of temperature, disappearance of cyanosis, and muscular movements of the upper, and especially the lower, extremities in bodies certified as dead. One of these, three-quarters of an hour after death, flexed and extended the forearms, clutched in his hand the bulb of the thermometer, and carried the arms from the side of the trunk on to the thorax. More remarkable movements of the muscles were observed in a woman just announced as dead of cholera on whom the Cæsarean operation was performed, the diaphragm being seen to ascend and descend. Puccinotti (the author of the classic "History of Medicine"), contemporarily with Betti, records similar phenomena in the same epidemic; while at Naples in the same year cases certified as dead and given over to the undertaker were rescued within a few minutes of interment. The narrow escape of one such case in the last cholera epidemic at Naples is recorded in the *Gazzetta d'Italia* of September 28th, 1873, the fortunate patient's name being Alfonso Lascala. "On a prouvé," writes Dr. le Bon ("De la Mort Apparente," Paris, 1866), "qu'on enterrait beaucoup de cholériques susceptibles d'être rendus à la vie."

SARCOMA OF THE OVARY AND OMENTUM SUCCESSFULLY REMOVED.

Il Morgagni, for June last, published a report by Dr. Cosmo Spadaro, of a successful operation performed by Professor A. d'Antona for sarcoma of the right ovary and of the omentum. The patient, A. S——, aged fifteen, from Salerno, was admitted into Professor Cantani's clinique last February. She first menstruated the previous July, and again in August, but not since. In September (five months before admission) she noticed in the right iliac fossa a tumour as large as a hen's egg. It grew rapidly, but only gave trouble by its weight. The tumour, largely lobulated and solid, filled the right iliac fossa, and extended up into the corresponding hypochondrium, the ascending colon being scarcely perceptible on percussion. The operation was performed on April 3rd. The omentum was extensively adherent, and its vessels were much enlarged. The pedicle, which was a long one, was tied, and dropped into the pelvis. Another tumour, as large as an orange, was then noticed between the folds of the omentum, and adhering to the great curvature of the stomach. That tumour having also been removed, and some vessels which fed it tied, the abdominal cavity was closed with ten sutures. Some febrile symptoms supervened, but abated in the course of thirty-six hours. Half the sutures were removed on the fourth day, and the remainder on the eighth. The patient was fully convalescent, and sat up in bed, on the tenth day. The tumour weighed sixteen pounds, and on section proved characteristically sarcomatous, and in one part encephaloid.

A CHAPTER OF ACCIDENTS.

THE case of which the following account is a brief description presents many points of interest, not only from a pathological, but also from a clinical and practical, point of view. The patient was a man aged twenty, who had a large tumour of the face, supposed to have been due to the extension of a malignant naso-pharyngeal polypus. An operation had already been performed, and the superior maxillary bone removed. When first seen by M. Verneuil the new growth was excessively vascular, and a distinct bruit was to be heard like that found in cases of arterio-venous aneurysm. As the tumour appeared to consist largely of erectile tissue, many surgeons who saw the case with M. Verneuil advised the employment of irritant injections with a view to setting up inflammation, and, it was hoped, subsequent atrophy. The result of the injections was not a happy one; much inflammation ensued, and frequent bleeding took place, the tumour increased in size and the patient's health obviously declined. Whilst matters were at this pass M. Verneuil resolved to ligature the common carotid on the same side of the neck as the tumour, with the object of controlling the hæmorrhage and relieving the inflammation.

Digitized by Google

For a brief period these objects were attained, but a large abscess formed in the tissues of the tumour, and finally burst outwards through the skin. Again, there was an interval of comparative comfort for the patient. At the end of this, however, an attack of erysipelas set in. The ligature came away on the fourteenth day, but the wound did not completely heal. Notwithstanding much local treatment, many sloughs and a piece of the carotid artery twelve millimetres long came away from the wound, and frequent hæmorrhage from this site ended in the death of sufferer. At the autopsy the sphenoid fossa was found to have been penetrated by the tumour, so that a projection the size of a nut was seen in the cranial cavity. The distal end of the carotid artery was perfectly obliterated; but a long search was needed before the remains of the cardiac end could be found in the putrid tissues of the wound. There was a recent thrombosis of the internal jugular vein; the vagus nerve is said to have been intact. All the viscera were healthy, if exception be made of a fatty liver. There were no metastatic abscesses. The brain was slightly inflamed at that part which was in contact with the tumour.

THE BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.

THE annual report issued by Dr. Thomas Savage, who has just entered into office as honorary secretary of this Society, is a highly satisfactory document. The members are 280, with a capital of £10,130. The annual average for the last five years shows grants, £390; income from investments, £370; total income, £679; total expenditure, £431; excess of total income over grants, £289; excess of total income over total expenditure, £248. In this prosperous institution the court of directors are able to answer promptly and with judicious liberality all deserving claims under their rules, and at the same time to add to their investments with a safe margin for eventualities. The subscriptions of a member close on reaching a total of £22 1*s.*; and for this comparative trifle two annuitants, widows of members, have received respectively the handsome totals of £1125 and £1247 10*s.* With such substantial advantages, it is not a little remarkable that the roll does not exceed 280, when the wide area from which members are eligible is taken into account. The Society's second rule provides that "any registered medical practitioner, regularly practising his profession within fifty miles of Birmingham, or within the distance of ten miles of the residence of any corresponding member, shall be eligible as a member of this Society."

TYPHOID FEVER AND PERFORATION OF THE GALL-BLADDER.

IN medical diagnosis we frequently have to deal with a question of probabilities. There can be no doubt, however, that a little more logic and less hazard are needed in dealing with clinical problems. M. Barbe has recently recorded the case of a man, aged twenty-six, who, whilst suffering from an attack of chronic jaundice, certainly due to obstruction of the bile-duct from a stone, appears to have been unfortunate enough to develop the signs and symptoms of typhoid fever. From the report given we gather that the fever, the nature of which cannot be called in question, was at about the eighth day of its course when the symptoms of peritonitis set in and the patient succumbed. At the necropsy the lymphatic structures of the small intestine, cæcum, ascending colon, and *stomach* were greatly swollen and even already partially ulcerated. It may be mentioned that the patient vomited black matter, and it would appear that this was altered blood derived from the ulceration of the lymphatic follicles in the stomach. The spleen was enlarged and diffluent. The liver was large, yet little stained with bile, notwithstanding the obstruction of the bile-duct, yellowish in places, tough, and resistant to the knife. The gall-bladder was found to be shrunken and empty of bile, but adherent to the transverse colon, and contained a large calculus. After laying it open an ulceration of greyish-black colour was seen at the base of the viscus; in two places the ulceration had gone on to perforation. M. Barbe discusses the relationship of the ulceration of the gall-bladder to the calculus and typhoid fever. Seeing that there was such a general affection of the lymphatic structures of the gastro-intestinal mucous membrane, and seeing that this affection had gone on to ulceration not only in the intestines, but also in the stomach, we think there exists considerable probability that the disease of the gall-bladder was largely due to the poison of typhoid fever. That the ulceration in the gall-bladder should have been deeper than elsewhere, and so attended with more serious consequences, is, perhaps, only to be expected from the presumably greater irritation resulting from the presence of a calculus as compared with whatever food might have been ingested and brought into contact with the tissues of the stomach and intestine.

SMALL-POX IN THE DIAMOND FIELDS.

THE pestilence still rages with undiminished virulence. White men and natives alike are falling victims to it. The area of distribution is unfortunately a very wide one, and for this reason the resources of the authorities are taxed to the utmost. From the local press we gather that Drs. Jameson and Wolff still maintain that the disease is not small-pox, and decline to admit that it is generally infectious and contagious. We sincerely trust the report does not correctly give the position of Drs. Jameson and Wolff with regard to an epidemic which has almost universally been declared to be small-pox. It matters but little now whether they consider it as such or as varicella. The wind has been sown and now the whirlwind is being reaped. It is to be hoped that the wreckage will be less than we fear is probable. The Cape Government has stated in Parliament that the only powers it possesses are, first, that of granting permission to the local authorities to raise means wherewith to arrest and stamp out the plague, and secondly, that of proceeding against those who on affidavit can be shown through wilful or culpable negligence to have been the cause of injury to the community. It is a sorry state of affairs that the Central Executive finds itself in, if its action is thus limited by the statute law. Cannot a short measure be passed giving greater control to the Sanitary Board? Clearly something is needed, if success is to be deserved, much less demanded.

CAPITAL PUNISHMENT IN FRANCE.

AT length it is beginning to be recognised in France that the brain of a decapitated criminal lives, and consciousness is maintained, for an appreciable time, which to the victim may seem an age, after death—an opinion we strongly expressed many years ago. This ghastly *fact*—as we have no doubt it is—being perceived, it is beginning to be felt that executions cannot any longer be carried out by the guillotine. Prussic acid is now proposed. If instantaneous death be desired, this is clearly inadmissible. The period taken to terminate life by poison of any kind must needs vary greatly with the individual. In not a small proportion of instances we fancy death by prussic acid would be considerably protracted, and although long dying is not so horrible as living after death—so to say—yet it is strongly opposed to the interests of humanity to protract the agony of a fellow-creature dying by the hand of justice. Electricity is another agent suggested. We doubt the pos-

Digitized by Google

sibility of applying this agent so as to destroy life instantly. We confess that, looking at the matter all round, we incline to think that hanging, when properly performed, destroys consciousness more rapidly and prevents its return more effectually than any other mode of death which justice can employ. It is against the bungling way of hanging we protest, not against the method of executing itself. That is, on the whole, the best, we are convinced.

THE ACCIDENT TO LADY SHUCKBURGH.

OUR readers will have seen in the daily papers accounts of a serious accident by which the life of Lady Shuckburgh has been placed in some danger from the bite of a mad dog. The wound, no doubt, has received prompt and careful attention, and we sincerely hope that evil consequences may be averted. It is, moreover, consoling for all in similar circumstances to know that bites of rabid dogs, even if not treated, do not invariably cause hydrophobia. The case before us, with the bite still recent, is one of those in which Professor Pasteur, in his recent communication on rabies before the Paris Academy of Sciences, held out a guarded hope of immunity by early inoculation with a modified virus. His words are worth quoting. After describing his researches, he says: "On this point [the suppression of hydrophobia by inoculation after a rabid bite] the first experiments which I have conducted give the greatest hopes of success. Thanks to the duration of incubation of rabies resulting from a bite, I have every reason to believe that one can surely bring about a protected state in the person bitten before the disease has had time to develop itself. While these first experiments give much colour to this view, it is necessary to multiply indefinitely such tests in the lower animals before therapeutic science will be hardy enough to extend their action to the human subject." It may be added that since these words were spoken M. Pasteur has shown, by an extended and apparently conclusive experiment, that his method of inoculation is protective in the case of dogs against the bites of rabid members of their own species.

THE GASTRIC SECRETION OF THE FŒTUS.

IT has been shown that if sulphindigotate of soda or iodide of potassium be given to a rabbit towards the end of pregnancy, these chemicals are always present in the liquor amnii, and have been occasionally discovered in the stomachs of the embryos. This latter fact has hitherto been explained as being the result of swallowing liquor amnii by the fœtus, and indeed has been cited as a proof that the fœtus does swallow liquor amnii under normal conditions. The absence of these salts from the rest of the body of the fœtus, or their extremely minute proportions if present, seemed to negative the idea of their secretion into the stomach from the fœtal blood. This subject has lately engaged the attention of Dr. Krukenberg, of Bonn, who proved first that iodide of potassium was as constantly found in the stomach as in the liquor amnii after subcutaneous injection in guinea-pigs and rabbits towards the end of pregnancy. He afterwards found that in guinea-pigs less advanced in pregnancy, the chorionic fluid (between chorion and amnion) contained the salt, and not the liquor amnii, while in this case also the stomach contained the iodide. This negatived the idea of fœtal deglutition and confirmed that of gastric secretion from the fœtal blood. The same results followed in rabbits before the final third of pregnancy, and in a cat and a bitch at the end of pregnancy the iodide was found to be present in the stomach but absent from the allantoic and amniotic fluid, and entirely or almost entirely absent from the fœtal tissues. He therefore concludes that the presence of the salt in the stomachs of immature fœtuses of rabbits and guinea-pigs (in which the liquor amnii does contain it) is explained by the cases of mature embryos of those animals, in which the liquor amnii does not contain it while the stomach does, and that in all cases it is essentially secreted from the fœtal blood. It seems probable that easily diffusible substances pass into the fœtus and are excreted from its stomach far more copiously than has been imagined. The great difference of excretion of the salt into the chorionic or amniotic fluid in different animals, or even in the same animal at different stages of pregnancy, is remarkable, and furnishes an additional proof of the danger of arguments from analogy.

THE RECENT CASE OF CHOLERA AT ALEXANDRIA.

A CORRESPONDENT at Cairo writes: The facts relative to the recent case of cholera are very simple, and were certainly not enough to cause a scare in Alexandria. It appears that an Austrian woman cook, aged forty, living in an Italian restaurant, had suffered from diarrhœa for a few weeks before July 13th, for which she had been treated by a medical man, and which did not prevent her from working as usual. On the night of the 13th she is stated to have had forty rice-water motions, accompanied twice by vomiting. She was taken to the European hospital early on the morning of the 14th, and had neither vomiting nor diarrhœa for several hours. Her condition on this morning was described by all the doctors who saw her as follows: facies choleraica, loss of voice, fall of temperature, foul tongue, intense thirst, severe cramp in calves and thighs, complete suppression of urine, collapsed pulse, and great mental anxiety. These symptoms abated slightly towards evening, when there was one liquid motion, followed for a time by very severe cramp in the thighs. On the 15th there was no more vomiting, the diarrhœa was insignificant, the voice had partly recovered its strength, and the cramps and suppression of urine had disappeared. Thereupon four doctors signed a bulletin to the effect that the case was one of "cholera nostras," and a fifth doctor stated that he would wait until the complete cure of the patient before affixing his name to the diagnosis. The patient is now convalescent, and there has been no suspicion of a second case. A case of cholera occurred, however, on board a French steamer in quarantine at Alexandria. The sick man and all the passengers were sent to the lazaretto, and the quarantine term was raised from seven days to ten. The whole official world of Egypt flocks to Alexandria this week to pay its respects to the Khedive, and to enjoy all forms of Bairam feasting. Fortunately for the general health, those who are most likely to give way to immoderate excess are not those who are now strictly observing the thirty days' fast. The health of the English army continues remarkably good; there being about 8 per cent. of sickness, of which 3 per cent. are due to venereal disease.

CRIMINAL ABORTION.

AN adjourned inquiry was held at University College Hospital, on July 31st, touching the death of Mary Trumble, aged thirty-two. The deceased was a single woman. Some nine years previous to her death she gave birth to a child still living. Her late illness commenced on or about July 10th, when she complained of diarrhœa and a bilious attack. On the 14th a medical man was called in, and he attended the deceased until her admission into hospital on the 20th. Up to that time it was supposed she was suffering from typhoid fever, and neither the doctor nor nurse suspected the actual state of affairs. Mr. Woolbert, the house-physician at University College Hospital, finding the woman in a moribund condition, was unable to make a definite diagnosis, but expressed his opinion that abortion might have taken place, and, acting upon that opinion, refused to give a death certificate

Digitized by Google

without having first made a post-mortem examination. The coroner, Dr. Danford Thomas, on the facts being laid before him, ordered an inquest to be held. On the first day of the hearing Mr. Woolbert detailed the nature of a number of wounds he discovered, and also other evidence which in his judgment conclusively proved that an abortion had been obtained by forcible means. There were two punctured wounds external to the vulva, such as might have been made with a knitting-needle or some such instrument. The vagina was extensively lacerated and bruised. The uterus together with the ovaries weighed thirteen ounces. On examining the interior a flocculent appearance was observed at the posterior part, clearly pointing to a placental attachment. Opposite this, and quite unconnected with it, was a rugged, broken surface of smaller dimensions. There were no anatomical signs of typhoid fever. As some little doubt was cast upon Mr. Woolbert's conclusions, the coroner ordered Mr. Pepper to investigate the case, and report the result at the adjourned inquest. This gentleman deposed that he entirely agreed with Mr. Woolbert that an instrumental abortion had been procured. He had ascertained that the wounds above described had been inflicted some days prior to death; he further found a small lacerated wound in the uterus, three-quarters of an inch from the external os, and in a direct line with the larger one on the anterior surface. In one ovary was a corpus luteum, measuring half by a quarter of an inch. Mr. Pepper stated he was quite certain that an abortion had been induced by violence, and that the injuries had been done by some one other than deceased. He was further of opinion that the instrument had been used by a person having some anatomical knowledge of the parts, as it had been steered directly through the os into the uterine cavity. He attributed the wound and bruises about the vagina and vulva to the clumsiness or nervousness of the operator. The cause of death was metro-peritonitis and septicæmia. It is matter of regret that the real condition of the deceased was not discovered during her lifetime, as then measures might have been taken with a view to combat the dangers which threatened and afterwards destroyed her life. Moreover, the means of bringing the perpetrator of the crime to justice were then ready to hand; now, with the death of the victim, the only reasonable expectation of doing so has vanished.

EASY LIQUEFACTION OF OXYGEN.

IT will be remembered that Messrs. Wroblewski and Olszewski some time ago succeeded in liquefying oxygen by the use of ethylene. M. Cailletet has searched for and found a body having a still lower boiling point than ethylene, and by means of which oxygen can be very readily liquefied. This substance is simply formene or marsh gas, which under slight pressure and cooled in ethylene, boiling under the ordinary atmospheric pressure, is resolved into an extremely mobile, colourless liquid, which in passing again into a gaseous state causes such a lowering of temperature that oxygen in its neighbourhood is immediately liquefied.

THE REPEAL OF THE PATENT MEDICINES STAMP ACT.

AT the recent meeting of the British Medical Association the following resolution, proposed by Professor Matthew Hay and seconded by Dr. Leech of Manchester, was adopted:—"That in the opinion of the section of Pharmacology and Therapeutics of the British Medical Association it is highly desirable that the Patent Medicines Stamp Act should be repealed, for the following reasons: (1) It is unjust to impose a tax on medicines; (2) the Act as recently interpreted promises greatly to impede the importation and use, especially in hospital practice, of medicines of foreign origin; (3) the Government label issued under the Stamp Act is taken advantage of by patent medicine manufacturers to give the appearance of Government endorsement to their productions, and lead the public to suppose that the properties of the medicines are sanctioned by authority." This resolution was brought before the final general meeting, and was referred to the Council to consider what action should be taken in the matter.

HOSPITAL SUNDAY FUND, 1884.

IT is gratifying to have to report that a sum in excess, by £100 or £200, of that of any previous year has been raised by the religious community of the metropolis in aid of the great cause of hospitals. Over £31,000 has to be distributed—viz., £29,026 to hospitals and £2257 to dispensaries. The generally satisfactory state of the institutions may be gathered from the fact that in only one instance was it necessary for the Committee of Distribution to press for the attendance of a deputation. The growing need for the fund and for its development is shown in the fact that forty-three more institutions than were assisted at the commencement of the fund will receive an award from the collection of this year. In conformity with Law XII., 4 per cent. of the total amount of collections—viz., £1400—is ordered to be set aside for the purchase of surgical appliances.

THE metropolitan police courts are, it is satisfactory to note, affording evidence of some degree of activity on the part of the vestries in respect of insanitary dwellings. During the last few days, magistrates' orders have been obtained for the abatement of nuisances and for the supply of arrangements and conditions essential to the health of the inhabitants of dilapidated houses.

WE are asked to state that the mural tablet to be erected in the Royal Victoria Hospital, Netley, in memory of the officers of the Army Medical Department who lost their lives in the Afghan and Zulu wars, has been designed and sculptured by Count Gleichen, and can be viewed between the hours of 11 and 6 at Count Gleichen's studio, St. James's Palace.

A CORRESPONDENT to the *Dumfries and Galloway Standard*, using the *nom de plume* "Sanitas," calls attention to the fact that the Crichton Institute and Southern Counties Asylum draw their water supplies from a well which has for its chief feeding-ground rocks over which the whole sewage of the town is supposed to pass.

A LUNACY COMMISSION consisting of eight members has been appointed by the Government of Victoria to inquire into and report upon the state and condition of asylums for the insane and inebriate, both public and private, in the colony. The first public meeting of the Commission was held on June 3rd.

THE Dewsbury guardians have withdrawn from their untenable position. At a meeting of the board on the 1st inst. they appointed public vaccinators for Mirfield and Thornhill. This submission on their part puts an end to the legal proceedings instituted against them by the Local Government Board.

WE learn that Drs. Klein and Heneage Gibbes sailed for India on Wednesday last in the Peninsular and Oriental steamship *Ancona*.

THE death is announced of Dr. Moreau, the distinguished alienist, and the pupil of Esquirol, in his eighty-first year.

THE Queen, with her characteristic grace and kindness, along with the Princess Beatrice, paid a visit to Dr. and Mrs. Royle at their villa during Her Majesty's stay at Claremont. This was the only house in the neighbourhood thus honoured by the Royal presence.

THE Queen has been pleased to appoint Sir Prescott Gardiner Hewett, Bart., F.R.S., to be one of Her Majesty's Serjeant-Surgeons in Ordinary, in the room of Mr. Cæsar H. Hawkins, F.R.S., deceased.

DR. THOMAS COLLINS has been re-elected representative on the Medical Council for the Apothecaries' Hall of Ireland for the ensuing year.

MR. CORLEY has been elected a Member of Council of the Royal College of Surgeons in Ireland. He was unopposed.

DR. KOCH ON THE CHOLERA.

AN important and influential conference[1] upon cholera was opened in Berlin at the Imperial Board of Health on the evening of July 26th. There were present Drs. v. Bergmann, Coler, Eulenberg, B. Fränkel, Gaffky, Hirsch, Koch, Leyden, S. Neumann, Pistor, Schubert, Skreczka, Struck, Virchow, and Wolffhügel. The conference had been called at the instance of the Berlin Medical Society, whose President, Prof. Virchow, explained that it was thought advisable Dr. Koch should in the first instance give a demonstration of his work before a smaller body than the whole Society, so that the proceedings might be fully reported in the medical press. He mentioned that Herr Director Lucanus and President Sydow had expressed their regret at being unable to be present, as well as many others, including Drs. von Lauer, von Frerichs, Mehlhausen, and Kersandt. Before the meeting Dr. Koch exhibited microscopical specimens and drawings of the cholera bacillus, and demonstrated the method of its preparation and cultivation. The preparations included specimens of choleraic dejections dried on covering glasses, stained with fuchsin or methyl-blue, and examined with oil immersion, one-twelfth, and Abbe's condenser; also sections of intestine preserved in absolute alcohol, and stained with methyl-blue. There were also cultures in gelatin, &c.

Dr. KOCH commenced by remarking that what was required for the prevention of cholera was a scientific basis. Many and diverse views as to its mode of diffusion and infection prevailed, but they furnished no safe ground for prophylaxis. On the one hand, it was held that cholera is a specific disease originating in India; on the other, that it may arise spontaneously in any country and own no specific cause. One view regards the infection to be conveyed only by the patient and his surroundings; the other that it is spread by merchandise, by healthy individuals, and by atmospheric currents. There is a like discrepancy in the views on the possibility of its diffusion by drinking water, on the influence of conditions of soil, on the question whether the dejecta contain the poison or not, and on the duration of the incubation period. No progress was possible in combating the disease until these root questions of the etiology of cholera are decided. Hitherto the advances in knowledge upon the etiology of other infective diseases have done little towards the etiology of cholera. These advances have been made within the last ten years, during which time no opportunity—at least not in Europe—has occurred to pursue researches; and in India, where there is abundant material for such research, no one has undertaken the task. The opportunity given by the outbreak of cholera in Egypt last year to study the disease before it reached European soil was taken advantage of by various Governments, who sent expeditions for the purpose. He had the honour to take part in one of these, and in accepting it he well knew the difficulties of the task before him, for hardly anything was known about the cholera poison, or where it should be sought; whether it was to be found only in the intestinal canal, or in the blood, or elsewhere. Nor was it known whether it was of bacterial nature, or fungoid, or an animal parasite—e.g., an amœba. But other difficulties appeared in an unexpected direction. From the accounts given in text-books he had imagined that the cholera intestine would show very slight changes, and would be filled with a clear "rice-water" fluid. He had not fully recollected the conditions met with in post-mortem examinations he had formerly made, and was therefore at first surprised to meet with quite a different state of things. For he soon found that in a large majority of cases remarkably severe lesions were present in the intestines. In other cases the changes were slighter, and eventually he met with some which to a certain extent corresponded with the type described in text-books. But it was some time, and after many inspections, before he was enabled to correctly interpret the varied changes met with. In spite of a most careful examination of all other organs and of the blood, nothing was found to establish the presence of an infective material, and attention was finally concentrated on the intestinal conditions. There were cases in which the lower segment of the small intestine, most marked immediately above the ileo-cæcal valve, extending thence upwards, was of a dark-reddish-brown colour, the mucous membrane being covered with superficial hæmorrhages. In many cases the mucous membrane appeared to be superficially necrosed, and covered with diphtheritic patches. The intestinal contents in such cases were not colourless, but consisted of a sanguinolent, ichorous, putrid fluid. Other cases showed a gradual transition to a less marked change. The redness was less intense, and was in patches, whilst in others the injection was limited to the margins of the follicular and Peyerian glands, giving an appearance which is quite peculiar to cholera. In comparatively few cases were the changes so slight as to consist in a somewhat swollen and opaque condition of the superficial layers of the mucous membrane, with delicate rosy-red injection, and some prominence of the solitary follicles and Peyer's patches. In such cases the intestinal contents were colourless, but resembling meal-soup rather than rice-water. In only a solitary instance were the contents watery and mucoid. Microscopical examination of the intestine and its contents revealed, especially in the cases where the margins of Peyer's patches were reddened, a considerable invasion of bacteria, occurring partly within the tubular glands, partly between the epithelium and basement membrane, and in some parts deeper still. Then he found cases in which, besides bacteria of one definite and constant form, there were others also accumulated within and around the tubular glands, of various size, some short and thick, others very fine; and he soon concluded that he had to do here with a primary invasion of pathogenic bacilli, which, as it were, prepared the tissues for the entrance of the non-pathogenic forms; just as he had observed in the necrotic, diphtheritic changes in the intestinal mucosa and in typhoid ulcers. Passing to speak of the microscopical characters of the contents of the bowel, Dr. Koch said that owing to the sanguinolent and putrescent character of these in the cases first examined, no conclusion was arrived at for some time. Thus he found multitudes of bacteria of various kinds, rendering it impossible to distinguish any special forms; and it was not until he had examined two acute and uncomplicated cases, before hæmorrhage had occurred, and where the evacuation had not decomposed, that he found more abundantly the kind of organism which had been seen so richly in the intestinal mucosa. He then proceeded to describe the characters of this bacterium. It is smaller than the tubercle bacillus, being only about half or at most two-thirds the size of the latter, but much more plump, thicker, and slightly curved. As a rule, the curve is no more than that of a comma (,) but sometimes it assumes a semicircular shape, and he has seen it forming a double curve like an S; these two variations from the normal being suggestive of the junction of two individual bacilli. In cultures there always appears a remarkably free development of comma shaped bacilli. These bacilli often grow out to form long threads, not in the manner of anthrax

[1] A detailed report is published in the Berliner Klinische Wochenschrift of Aug. 4th.

Digitized by Google

bacilli, nor with a simple undulating form, but assuming the shape of delicate long spirals, a corkscrew shape, reminding one very forcibly of the spirochæte of relapsing fever. Indeed, it would be difficult to distinguish the two if placed side by side. On account of this developmental change, he doubted if the cholera organism should be ranked with bacilli; it is rather a transitional form between the bacillus and the spirillum. Possibly it is a true spirillum, portions of which appear in the comma shape, much as in other spirilla—e.g., spirilla undula, which do not always form complete spirals, but consist only of more or less curved rods. The comma bacilli thrive well in meat infusion, growing in it with great rapidity. By examining microscopically a drop of this broth culture the bacilli are seen in active movement, swarming at the margins of the drop, interspersed with the spiral threads, which are also apparently mobile. They grow also in other fluids—e.g., very abundantly in milk, without coagulating it or changing its appearance. Also in blood serum they grow very richly. Another good nutrient medium is gelatine, wherein the comma bacilli form colonies of a perfectly characteristic kind, different from those of any other form of bacteria. The colony when very young appears as a pale and small spot, not completely spherical as other bacterial colonies in gelatine are wont to be, but with a more or less irregular protruding or jagged contour. It also very soon takes on a somewhat granular appearance. As the colony increases the granular character becomes more marked, until it seems to be made up of highly refractile granules, like a mass of particles of glass. In its further growth the gelatine is liquefied in the vicinity of the colony, which at the same time sinks down deeper into the gelatine mass, and makes a small thread-like excavation in the gelatine, in the centre of which the colony appears as a small white point. This, again, is peculiar; it is never seen, at least so marked, with any other bacterium. And a similar appearance is produced when gelatine is inoculated with a pure culture of this bacillus, the gelatine liquefying at the seat of inoculation, and the small colony continually enlarging; but above it there occurs the excavated spot, like a bubble of air floating over the bacillary colony. It gives the impression that the bacillus growth not only liquefies the gelatine, but causes a rapid evaporation of the fluid so formed. Many bacteria also have the power of so liquefying gelatine with which they are inoculated, but never do they produce such an excavation with the bladder-like cavity on the surface. Another peculiarity was the slowness with which the gelatine liquefied, and the narrow limits of this liquefaction in the case of a gelatine disc. Cultures of the comma bacillus were also made in Agar-Agar jelly, which is not liquefied by them. On potato these bacilli grow like those of glanders, forming a greyish-brown layer on the surface. The comma bacilli thrive best at temperatures between 30° and 40° C., but they are not very sensitive to low temperatures, their growth not being prevented until 17° or 16° C. is reached. In this respect they agree with anthrax bacilli. Koch made an experiment to ascertain whether a very low temperature not merely checked development but killed them, and subjected the comma bacilli to a temperature of – 10° C. They were then completely frozen, but yet retained vitality, growing in gelatine afterwards. Other experiments, by excluding air from the gelatine cultures, or placing them under an exhausted bell jar or in an atmosphere of carbonic acid, went to prove that they required air and oxygen for their growth; but the deprivation did not kill them, since on removing them from these conditions they again began to grow. The growth of these bacilli is exceptionally rapid, quickly attaining its height, and after a brief stationary period as quickly terminating. The dying bacilli lose their shape, sometimes appearing shrivelled, sometimes swollen, and then staining very slightly or not at all. The special features of their vegetation are best seen when substances which also contain other forms of bacteria are taken—e.g., the intestinal contents or choleraic evacuations mixed with moistened earth or linen and kept damp. The comma bacilli in these conditions multiply with great rapidity so as to far outnumber the other forms of bacteria, which at first might have been in far greater abundance. This state of affairs does not last long; in two or three days the comma bacilli begin to die off, and the other bacteria to multiply. Precisely the same thing takes place in the intestine, where, after the rapid initial vegetation is over, and when exudation of blood occurs into the bowel, the comma bacilli disappear and putrefactive bacteria predominate. Whether the occurrence of putrefaction is inimical to the comma bacilli has not been proved, but from analogy it is very probable. At any rate, it is important to know this for certain, for if it be so then the comma bacilli will not thrive in a cesspit, and then further disinfection would be unnecessary. These bacilli thrive best in fluids containing a certain amount of nutriment. Experiments have not yet shown the limits in this respect, but Koch has found them capable of growing in meat broth diluted ten times. Again, if the nutrient medium become acid in reaction their growth is checked, at least in gelatine and meat infusion; but, singularly enough, they continue to grow on the surface of boiled potato which has become acid, showing that all acids are not equally obnoxious to them. But here, as with other substances which hinder their growth, they do not kill the bacilli. Davaine has shown that iodine is a strong bactericide. He experimented with anthrax bacilli in water to which iodine was added, and the bacilli were destroyed. But practically the organisms have to be dealt with in the alkaline contents of the bowel, or in the blood or fluids of the tissues, where iodine cannot remain in the free state. Koch found that the addition of an aqueous solution of iodine (1 in 4000) to meat infusion, in the proportion of 1 in 10, did not in the least interfere with the growth of the bacilli in that medium. He did not pursue this line of inquiry, seeing that in practice larger quantities of iodine than that could not be given. Alcohol first checks the development of the comma bacilli when it is mixed with the nutrient fluid in the proportion of 1 in 10, a degree of concentration which renders it impracticable for treatment. Common salt was added to the extent of 2 per cent., without influencing the growth of the bacilli. Sulphate of iron, in the proportion of 2 per cent., checks this growth, probably by precipitating albuminates from the fluids, and possibly also by its acid reaction; certainly it does not seem to have any specific disinfecting action—i.e., in destroying the bacilli. Indeed, Koch thinks that the admixture of sulphate of iron with fæcal matter may arrest putrefaction and really remove what may be the most destructive process to the comma bacilli. Hence he would distinguish between substances which merely arrest putrefaction and those which are bactericidal; for the former may simply serve the purpose of preserving the infective virus. Among other substances which prevent the growth of the comma bacilli may be mentioned: alum, in solutions of the strength 1 in 100; camphor, 1 in 300; carbolic acid, 1 in 400; oil of peppermint, 1 in 2000; sulphate of copper, 1 in 2500 (a remedy much employed, but how much would really be needed merely to hinder the growth of the bacilli in the intestine!); quinine, 1 in 5000; and sublimate, 1 in 100,000. In contrast with the foregoing measures for preventing the growth of these bacilli is the striking fact that they are readily killed by drying. This fact is proved by merely drying a small drop of material containing the bacilli on a cover-glass, and then placing this over some of the fluid on a glass slide. With anthrax bacilli vitality is retained for nearly a week; whereas, the comma bacillus appears to be killed in a very short time. Thus it was found that although vitality was retained—depending largely upon the number of bacilli—for a short time, yet withdrawal of the nutrient fluid for an hour or even less often sufficed; and it never happened that the bacilli retained vitality after a deprivation lasting twenty-four hours. These results would seem to point to the fact that the comma bacillus does not, like the organisms of anthrax and vaccinia, pass into the resting state (Dauer-zustande) by drying; and if so it is one of the most important facts in the etiology of cholera. Much, however, remains to be done, especially with regard to the soiled linen of cholera patients being kept in a damp state. He found that in soiled articles, when dried for a time, varying from twenty-four hours and upwards, the comma bacilli were quite destroyed. Nor was the destruction delayed by placing choleraic excreta in or upon earth, dry or moist, or mixed with stagnant water. In gelatine cultures the comma bacilli can be cultivated for six weeks, and also in blood serum, milk, and potato, where anthrax bacilli rapidly form spores. But a resting state of the comma bacilli has never been met with—a very exceptional thing in the case of bacilli; and another reason why the organism must be regarded rather as a spirillum than a bacillus. For the spirilla require only a fluid medium, and do not, like the anthrax bacilli, thrive in the dry state. It is quite unlikely that a resting state of the comma bacillus will ever be discovered; and, moreover, its absence harmonises with our knowledge of cholera etiology.

(To be continued.)

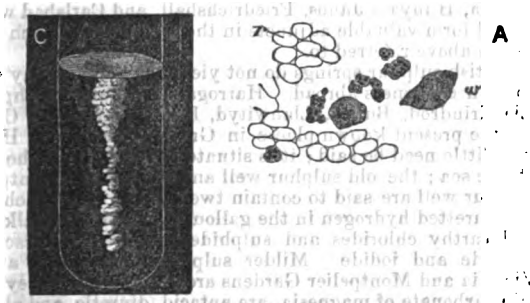
THE

BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.



WE propose, in a series of articles, to place before our readers descriptions and illustrations of the chief objects for inspection in the Biological Laboratory of the International Health Exhibition, so ably directed by Mr. Watson Cheyne. In presenting these articles we have aimed at as much brevity as is consistent with lucidity, and have attempted to render the information as interesting and clear as possible by the employment of neat woodcuts. Thus we hope that most of what is at present really known on the subject of bacterial pathology will be brought together in so small a compass as shall be within the limits of leisure which are afforded even to busy practitioners. Moreover, it is our wish to make these articles serve as a catalogue *de luxe* to the Biological Laboratory, our desire, also, being to stimulate the study of the objects themselves.

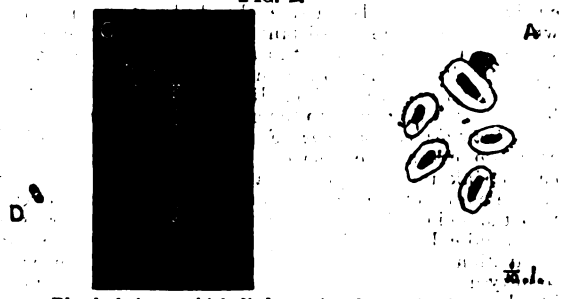
MICROCOCCUS TETRAGENUS.

This organism is frequently present in phthisical sputa, when destruction of the lung is making rapid progress. When unstained, it closely resembles Sarcinæ. When stained, the groups of which it is composed are seen to be made up of micrococci arranged in fours, the individual cocci lying at regular distances from one another, embedded in a faintly staining hyaline substance. The average diameter of a group of four is about one-third that of a red blood-corpuscle.

In test-tube cultivations[1] (C, Fig. 1), the colonies present

FIG. 1.

A, Blood of a guinea-pig which died six days after inoculation. Objective $\frac{1}{10}$ in. *r*, Red corpuscles, unstained. *w*, White corpuscles. C, Test-tube cultivation in gelatinised meat infusion.[1]



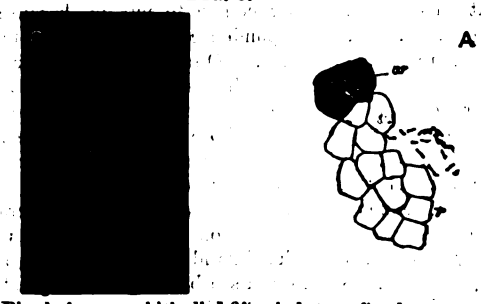
large, clearly defined, cushion-like masses along the course of the needle, which grow to a considerable size. When the micrococcus is inoculated into guinea-pigs and mice, they die in from two to ten days. The characteristic groups of four are found in the capillaries of all the organs, and generally large masses occur, which, when they form in the spleen, may burst through the peritoneal coat and set up peritonitis. The organism does not affect rabbits.

THE BACILLUS OF CHICKEN CHOLERA.

This is a disease of poultry. It is characterised by an inflammation of the duodenum attended with hæmorrhage, and the affected animal becomes profoundly drowsy. The blood is found to contain very minute bacilli, which have the peculiarity of staining deeply at the ends, while the tract between remains unstained, except at the surface. (Fig. 2, D.)

Test-tube cultivations (Fig. 2, C) show minute globular colonies, which never attain any considerable dimensions. They form an opaque growth, marking out the track of the needle. Fowls and pigeons inoculated from the cultivations

FIG. 2.

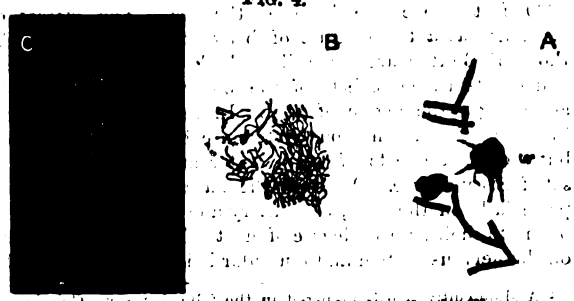


A, Blood of pigeon which died seventeen hours after inoculation from a cultivation of this bacillus. The minute bacilli are seen adhering to the oval nucleated blood-corpuscles. Objective $\frac{1}{10}$ in. C, Test-tube cultivation. D, Diagram of a single bacillus, to show the deeply staining ends, and the faintly stained band between them.

generally die in the course of from seventeen to twenty hours, and the bacilli are found in great numbers in the blood.

BACILLUS OF MOUSE SEPTICÆMIA.

FIG. 3.



A, Blood of mouse which died fifty-six hours after inoculation. Objective $\frac{1}{10}$ in. *r*, Red corpuscles, unstained. *w*, A white corpuscle, stained. C, Test-tube cultivation.

The bacilli of mouse septicæmia are frequently present in decomposing fluids. They are very minute, measuring ·8 to 1 μ in length (Fig. 3, A).

Test-tube cultivations (Fig. 3, C) present a very delicate haziness round the track of the inoculating needle, which contrast strikingly with the opaque colonies formed by other organisms. When the bacillus is inoculated into house mice they die in from forty to seventy-two hours, and the bacilli are found in the blood, frequently within the white corpuscles. The bacillus only affects rabbits and guinea-pigs locally; when inoculated into the ear redness and swelling are produced, which spread over the ear, and disappear in five or six days. After an attack of the disease the rabbit is found to be incapable of being again infected, at least for some time.

BACILLUS ANTHRACIS.

FIG. 4.

A, Blood of an animal inoculated with the bacillus anthracis. Objective $\frac{1}{10}$ in. B, Appearance of the border of a growing patch of anthrax [illegible] (see footnote 2), objective $\frac{1}{10}$ in. C, [illegible].

This disease affects sheep, cattle, and other animals. In man it takes the form of "woolsorters' disease" and

[1] Test-tube cultivations are prepared as follows. Gelatinised meat infusion is introduced into a test-tube which has been plugged with cotton-wool and sterilised by heat. The whole is then steamed for half an hour on three successive days, and allowed to solidify. When a cultivation is started, a sterilised platinum needle is dipped into the material to be examined, and then plunged into the preparation in the tube, the cotton-wool plug being removed for the purpose. The organisms thus introduced grow along the track of the needle.

Digitized by Google

"malignant carbuncle." The bacilli are present in the blood in large numbers. In the case of malignant carbuncle they are found in the tissues of the affected part. The organism is one of the largest bacilli, and when grown on cultivating materials outside the body it forms spores, which are extremely resistant to heat and chemical antiseptics. The spores are not formed in the living body.

Slide cultivations[2] show a mass of fine threads, towards the periphery of which the individual chains of bacilli may be seen extending out into the gelatine (Fig. 4, B).

In *test tube cultivations* (Fig. 4, C) the growth of the organism causes the gelatine to become liquid, and the bacilli sink in the liquid as a light flocculent precipitate. At the border of the liquid, where the growing bacilli extend into the solid gelatine, fine branching filaments are seen. Many animals are affected by it. The smallest trace of a cultivation inoculated into a mouse kills it in from twenty to forty hours; and the bacilli are found abundantly in the blood and swollen spleen.

HOME HEALTH RESORTS.

IT is not our intention, in writing this article on Health Resorts at Home, to recommend any particular set of places. The aim we have in view is to justify and amplify by a statement of facts, in more or less detail, the position which we took up in our last issue but one. We are persuaded that this is the proper course to pursue, because of the large amount of correspondence which the annotation referred to brought forth. Our readers will remember that our contention was that spas and places of health resort existed at home in sufficient abundance and in essential quality equal to those on the Continent. Individuals and families who are on the look-out for suitable places had better consult their ordinary medical advisers. Though we may not enter largely into the consideration of the excellent watering-places on the south and east coasts, we by no means infer that inland resorts are to be preferred to the seaside. Sea air and sea bathing are unquestionably powerful agencies in invigorating the constitution in large classes of individuals not necessarily coming under the category of invalids. First of all, it is necessary to point out that a residence at any of the spas implies considerably more than the mere taking of the waters or baths. The patient is influenced by many other agencies, each of which must be taken into consideration in any particular case. Change of climate, scene, diet, exercise, social habits, and occupation, and travelling, all play their part in the good results of so-called balneo-therapeutics.

Let us suppose that the doctor advises a course of simple thermal waters, say, for cases of chronic rheumatism, gout, or affections believed to be related in some way to these diatheses. The Continent being closed, where can the patient be sent? Bath and Buxton both possess fine hot springs. The former city has only a slight elevation, about 100 feet; the latter place is nearly 1000 feet above the level of the sea. The waters of Bath are at a temperature of between 100° and 120° F., those of Buxton are generally a little over 80°. The local and constitutional effects of the waters vary considerably according to the degree of heat. In the waters of Buxton the circulation and nervous system are but little influenced, but the other effects of warm water are all obtained in a satisfactory degree. At Bath the natural waters act more powerfully on the skin, circulatory and nervous apparatus, owing to their greater degree of heat. The soothing effects on the nervous system and muscular irritability are perfectly obtained with *warm*, rather than *tepid* or *hot* baths of water—that is, at a temperature of about 98°. Common salt or muriated saline waters may be had in plenty in England. There is Droitwich, perhaps the strongest of all brines, and possessing good arrangements; Nantwich, Middlewich, Woodhall, and Harrogate. Leamington and Cheltenham likewise contain common salt, in addition to sulphate of soda. Woodhall is very rich in iodides. These waters are of great value in deficient action of the skin; in tendencies to rheumatic fever or bronchitis; in cases of retarded convalescence from acute and chronic illness; in swelling of joints, the results of inflammatory action; in various chronic disorders of the system, such as scrofula and sluggish conditions of the digestive organs. The places named may be regarded as substitutes for Kissingen, Homburg, Kreuznach, Pyrmont, Wiesbaden, Baden-Baden, and other Continental spas.

With regard to alkaline waters it must be confessed that, so far as is at present known, there are no natural British waters which are so rich in the essential element (carbonate of soda) as some of the French and German springs. But where the alkaline waters are specially indicated, as in many forms of dyspepsia, gout, tendency to gall-stones, diabetes, and chronic catarrhal states, the imported waters of Vichy, Apollinaris, Bilin, or Wilhelmsquelle may be employed in conjunction with residence at one or other of the English resorts. Of waters whose chief constituent is either sulphate of soda or magnesia the British Isles possess their fair share. Leamington, Cheltenham, Scarborough, Purton Spa, and Epsom all rejoice in springs of a bitter taste, and containing the sulphates in greater or less proportion. The waters of the first two places mentioned are also rich in common salt. The bitter waters are valuable in habits of constipation with sluggish portal circulation, in tendency to hæmorrhoids, in congestion and enlargement of the liver and spleen, in some varieties of dyspepsia, in gall-stones, lithæmia, and diabetes. Stout plethoric persons do better on these waters than on the muriated saline waters. Here it is but just to mention that Pullna, Hunyadi János, Friedrichshall, and Carlsbad waters would form valuable adjuncts in the treatment of such cases as are above referred to.

British sulphur springs do not yield the palm in any sense to their congeners abroad. Harrogate, Moffat, Strathpeffer, Llandrindrod, Builth, Llanwityd, Lisdoonvarna (co. Clare), are the present known places in Great Britain. Of Harrogate little need be said; it is situate 600 feet above the level of the sea; the old sulphur well and the strong Montpelier sulphur well are said to contain twenty-five cubic inches of sulphuretted hydrogen in the gallon of water, with alkaline and earthy chlorides and sulphides, as well as traces of bromide and iodide. Milder sulphuretted springs at the Victoria and Montpelier Gardens are also in use; they contain carbonate of magnesia, are antacid, diuretic, and alterative. The social resources of Harrogate and the pleasant climate attract many classes of invalids, but the most suitable cases for treatment by the waters are—dyspepsia with inactivity of liver and bowels, especially when due to high living; constipation, obesity, swellings of joints and glands, chronic skin diseases, gout, rheumatism, and syphilis; some cases of disordered menstruation, and also some of incipient phthisis, may be sent to Harrogate with advantage. Moffat, in the upper part of Annandale, is 850 feet above the level of the sea, with a good climate and picturesque surroundings. The cold waters contain two and a half cubic inches of sulphuretted hydrogen in the pint of water, also twenty-two grains of chloride and two grains of sulphate of soda. Strathpeffer is a rising spa in Ross-shire, and has several cold sulphur springs as well as chalybeate waters of some value, as Mr. Berkeley Hill pointed out in the last volume of THE LANCET, p. 703. Llandrindrod, Builth, and Llanwityd are situate in Radnorshire; the climate at these places is pure and bracing. Chalybeate waters may be found fairly pure at Tunbridge Wells, Strathpeffer, and Harrogate. At Brighton there is a spring, now but little used, which contains sulphate of iron in small amount. Malvern, Bournemouth, Sandown, and many other health resorts possess chalybeate waters more or less available. The various forms of anæmia are most benefited by these waters, especially when the "poorness of blood" is due to hæmorrhage, suppuration, and previous acute or chronic disease. The chylopoietic viscera must, however, be in good working order. In anæmia associated with congestive states of the liver and intestines, a previous course of saline water is generally indicated. Cases of

[2] A slide cultivation is prepared in the following way. Gelatinised meat infusion which has been rendered sterile by heat is poured on a sterilised glass slide, and allowed to solidify. A sterilised platinum wire is then dipped into a growth of the organism which is to be examined, and drawn rapidly over the surface of the preparation on the slide. The bacteria are sown at intervals along the track of the wire, and as they grow form characteristic colonies. They may be observed in process of growth under the lower powers of the microscope.

Digitized by Google

neuralgia, sterility, and impotency may be benefited by the use of the iron waters, which act by invigorating the whole constitution.

Earthy and calcareous waters, so called, are rather scarce in Great Britain. The waters of Bath, Buxton, and Bristol, however, contain a certain proportion of the carbonates and sulphate of lime and carbonate of magnesia. These waters are of value in digestive troubles with tendency to acidity and diarrhœa. They may be employed in osteomalacia, rickets, and tuberculosis, and in some cases of eczema and psoriasis. Ilkeatone, near Nottingham, is a sparkling water, the carbonic acid of which holds carbonates of lime and magnesia in solution.

We cannot conclude this brief outline without expressing our belief that the increasing call for home health resorts would be followed by a great improvement of already existing spas, with a further development of their resources, and, moreover, looking to the geological conformation of these islands, we are strongly of opinion that judicious borings would lead to the discovery of deeply rolling watercourses, the waters of which might be rich in many of the constituents in which British waters in present use are wanting.

CHOLERA AND QUARANTINE.

THE cholera epidemic in the south of France still continues to subside, both in Marseilles and Toulon, and also in the other localities to which it had spread. In Italy the imported disease makes no substantial headway, and it may be hoped that with due sanitary precautions it will not now do so. Two further arrivals of infected vessels in this country have so far been unattended with any harm. At Cardiff the orders of the Local Government Board have been fully complied with in the case of the recently arrived vessels on which deaths had occurred since leaving Marseilles, and the system on which the Government relies has proved successful.

Two systems have now been fully tested. A large number of European countries, notably Italy and Spain, have trusted to the old quarantine measures with sanitary cordons. England, Switzerland, Germany, Austria, Holland, and Belgium have left their ports and their land boundaries free from these antiquated encumbrances. All the latter countries have hitherto remained free from the infection, although in our own country alone has the alternative system of inspection and isolation been in any way put to the test. Of the two countries where quarantine has been relied on, Spain has hitherto remained free from imported cholera; but in Italy, where the sanitary cordon has been maintained with the utmost stringency practicable, and where the lazarettos still contain some thousands of persons who entered the country quite free from infection, the disease has spread to a number of neighbouring places, and has already caused some thirty deaths. This result has led many Italians to inquire whether the quarantine game is worth the candle. The *Opinione* points to the fact that the country has surrounded itself with a Chinese wall, but that the disease has, notwithstanding, found an entrance; whilst the countries trusting to the system of inspection and isolation which received the assent of the last Vienna Conference have entirely escaped. Hygienically, nothing has been gained to Italy; whereas, commercially, the loss has been great. And not only so, but the very lazarettos themselves are so disgracefully organised from a health point of view, that the Italians are by no means clear that these institutions have not themselves tended to bring about the very conditions favourable to the development of the cholera poison by the aggregation of large numbers of persons under circumstances of the most unwholesome sort. Filth in its various and most offensive forms seems to reign along the line of this cordon, which is misnamed "sanitary," and persons who have been detained there have sickened and died in consequence, some after they have been permitted to leave. We thus have over again, although on a much smaller scale, the Egyptian experience of 1883—namely, stringent quarantine measures, and cholera not only passing through them as if they did not exist, but in all probability aggravated by their very existence. All modern experience thus tends to prove the wisdom of the English system, and it is highly probable that the abandonment of quarantine, as hitherto carried out, may, as regards many European countries, be the outcome of the epidemic of 1884.

It has been ascertained that cholera made its appearance at Marseilles last year, a case of cholera, followed by death having occurred at the hospital, in a room containing numerous other patients. The disease made a good many victims. The mayor, who was immediately advised of the fact, proceeded to the hospital. Energetic measures were taken to prevent further contagion, and in order to avoid panic in the town the mayor solicited and secured the silence of all persons aware of the facts. The head surgeon, two house surgeons, a warder, and two sisters of mercy took an oath to divulge nothing, and this oath was strictly kept till the 4th inst., when the circumstance was made known to the Medical Committee. Dr. Poucel delivered an address on the 6th inst. to the Medical Society of Marseilles on the Propagation of Cholera. He inclines to think, with Dr. Colin, in opposition to Dr. Koch's theory, that the germs are conveyed in the air. Dr. Jules Patras, a medical man attached to the Bureau d'Assistance, has succumbed to the epidemic after an illness of only a few hours. He is the first physician in Marseilles who has been struck down by cholera. At Rome the total number of persons in quarantine on the 5th inst. was 3025. At Toulon further complications are threatening, typhoid fever and small-pox having made their appearance among the convalescents at the Bon Rencontre and St. Mandrier establishments.

The health of Paris continues to be satisfactory, the deaths during the week ending the 2nd inst. being 993, as compared with 1062 in the previous week. One death was attributed by the medical men to cholera, the victim being a worker in copper. He was carefully isolated. There were four fatal cases of diarrhœa. The number of strangers leaving Paris is still slightly in excess of the arrivals—viz, 23,489, against 22,314. This is, of course, very unusual at this season.

A Bill has been introduced by Mr. Gray, M.P., with a view to making better provision against cholera and other epidemic diseases.

On the 30th ult. Professor de Chaumont made an exhaustive inquiry as to the sanitary precautions taken in Portsmouth town and garrison in view of a possible outbreak of cholera. The result of the inquiry is believed to be satisfactory, but it will not be known until the official report is made.

Some uneasiness has been caused at Northampton by an outbreak of English cholera. The town all the summer through has been suffering from scarcity of water. In their extremity the inhabitants have had recourse to impure springs, and the sewers have given off noxious exhalations for want of flushing. Several members of the family in which cholera first broke out have been affected.

QUARANTINE AND INFECTED PORTS.

NOTICES to the following effect have been published in the *London Gazette* of the 1st and 5th inst.:—

A quarantine of five days is imposed at the frontier of the Tyrol on all persons entering Italy.

Vessels with cholera patients on board, and bound for Norwegian ports, are to be taken by the pilots to the quarantine station at Christiansund.

All vessels arriving at Gibraltar from France are required to quit the port without communication, save under special circumstances.

At Constantinople the quarantine on arrivals from France has been raised to fifteen days, and on arrivals from Brindisi, Trieste, Leghorn, Spezzia, and the Black Sea ports to ten days. Travellers from the above and other infected ports will not be allowed to disembark at Scutari until they have completed quarantine in Corfu.

Arrivals at Teneriffe of vessels from British possessions in the Mediterranean which have sailed since July 16th will be subjected to quarantine.

The quarantine at Bagdad against arrivals from Bedra Jassan and neighbourhood has been removed.

A PLOT of ground, five acres in extent, has just been secured at Bolton-le-Moors on which to build a convalescent home, for the erection and endowment of which £30,000 was in 1870 left by the late Mr. Stephen Blair.

CASSAN *VERSUS* FYFE.

THE report of a trial of great interest and of grave importance to medical men, at the recent assizes at Lincoln, has reached us. Judging from the report, the facts are briefly these. The action was for slander, in which Mr. Theodore Cassan, L.R.C.P. Edin., M.R.C.S., of Gainsborough, was the plaintiff, and Dr. George Fyfe, of the same place, was the defendant. It is not without interest to notice some of the antecedents of these gentlemen. Mr. Cassan, before settling in Gainsborough, had been house-surgeon of the Training Hospital at Tottenham and house-surgeon of the Royal South Hants Infirmary. Dr. Fyfe had been house-surgeon of the Edinburgh Infirmary, and also of the Chester Infirmary. Clearly they are both gentlemen of experience in surgery, and should be alike capable of appreciating the difficulties and amenities of surgical practice. The slander complained of will appear from a brief statement of the case. On Friday, Feb. 1st, about half-past twelve in the day, Mr. Cassan, who is surgeon to the Britannia Sick Club, with about 1800 or 1900 members, and giving its surgeon about £360 a year, was applied to at his surgery by a member of the club named Howard, suffering with retention from old stricture of the urethra. Mr. Cassan had attended Howard in similar circumstances three years before. On this occasion matters were made worse by recent drinking, and by Howard being actually under the influence of drink when he first applied for relief of retention. Mr. Cassan at first failed to pass a catheter, but after giving Howard a draught composed of bromide and henbane, and enjoining half an hour's rest, succeeded without any difficulty whatever. He emptied the bladder completely, and gave the patient some medicine. He also told him that he was in a bad state, and advised him to go into the Lincoln Infirmary at once. The next day he called at Howard's house, used the catheter, and repeated his advice to go to the hospital. This he refused to do, saying that Mr. Cassan had pulled him through before, and would do so again. On Sunday, according to Mr. Cassan's account, Howard was much better, and had passed a good deal of urine. He did so in his presence. He still had symptoms of great constitutional disturbance, such as might be expected in a man of his habits, with an old stricture. On the Monday Mr. Cassan found him "much worse." He had much pain; he had passed no urine since the previous evening; he was very drowsy, and his pulse was failing. Mr. Cassan again introduced the catheter and emptied the bladder. He came to the conclusion that the patient would die. On Tuesday he was visited by Mr. Cassan's qualified assistant, Mr. Tatham, but refused to have the catheter passed, saying that he had voided urine in the bath. On Wednesday, when the assistant called again, Mr. Tatham found that Dr. Fyfe had been called in. On Thursday the patient died. The action for slander arose out of reports of the language held by Dr. Fyfe in regard to the previous treatment adopted by Mr. Cassan. About this there was the discrepancy, not unusual, between what the patient's friends reported (and in this case confirmed by other evidence of persons officially connected with the club) the doctor had said to them, and what he admitted having said. According to the former version, Dr. Fyfe had said that in the course of his experience he had never seen a man more shamefully treated; that the penis was black; that instruments must have been forced; and that the internal injuries done by these must have been as great as the external. Mr. Wharton, the vice-chairman of the club, said that Dr. Fyfe said to him, in answer to a question, that he "thought he could have cured the patient, and that any competent surgeon could have done so if he had been called in at first." When Mr. Cassan heard of these reports, he immediately applied to Dr. Fyfe by note for an explanation of them and a denial. He did this early on the Sunday morning following Howard's death, with the hope partly of securing a post-mortem examination before the funeral, which was to be held on that day. The envelope carrying Mr. Cassan's letter was returned by Dr. Fyfe with the following reply in pencil:—

"DEAR SIR,—I know nothing of the reports you allude to.—Yours faithfully, GEORGE FYFE."

The case became more serious for Mr. Cassan as the reports and complaints of the widow and friends reached the committee and officers of the club. The club appointed a committee to inquire into the facts, and the evidence of the widow and of one or two friends, and of the vice-chairman of the club and other officers, made the case a very long one, and, as it proved, serious in its conclusion. It is due to Dr. Fyfe to say that he disavowed many of the strong statements attributed to him, and that he declared that the accounts he received of the relief afforded by Mr. Cassan were much less favourable than those given in the evidence of the plaintiff and his assistant. He did not admit having said he could have "cured" the patient, only that he could have "relieved" him. In the end the Judge ruled that the statements attributed to Dr. Fyfe had not been proved, except, perhaps, such as were made to the representatives of the club. And—here is the serious part of the trial—he decided that these were not volunteered, that they were elicited as answers to questions, and that therefore they were "privileged." The question of privilege is one of law: for a judge, and not for a jury. Accordingly, his Lordship took it into his own hands, and directed the jury to find for the defendant, but agreed to stay execution for a fortnight, within which time notice of appeal must be given.

As leave has been granted for an appeal, and the matter is therefore *sub judice*, we reserve comment on the above important case.

ARMY MEDICAL SCHOOL, NETLEY.

THE forty-eighth session of the above school terminated on the 4th inst., when the results of the final examinations for commissions in the Medical Departments of the British and Indian Services were declared, the prizes awarded, and the business of the term concluded.

Lieut.-General Sir George Willis, K.C.B., commanding the southern district, attended by his staff and the principal medical officer of the district, arrived at Netley from Southsea at 12.30 P.M., and immediately proceeded to the lecture hall, where the staff of Netley Hospital and their guests, with the professors of the school and other visitors, were assembled. The Director-General of the Medical Department and the Physician to the Council of India were unable to attend, and we regret to say that Surgeon-General Murray, principal medical officer of the Royal Victoria Hospital, was also absent from indisposition.

The usual official documents reporting the work of the session were read, with the names of the surgeons on probation for both services reported fit to receive commissions according to the list printed in another column. It will be seen that the Herbert Prize of £20, the Montefiore Medal, with the same sum in money for Military Surgery, and the Martin Memorial Gold Medal for Military Medicine were won by Mr. J. H. T. Walsh, of H.M. Indian Service. The second Montefiore Prize for Military Surgery was gained by Mr. G. B. Russell, of the Army Medical Department. The Parkes Memorial Bronze Medal for Hygiene was awarded to Mr. C. Birt, of the same service. Mr. H. Hendley, of H.M. Indian Service, was the successful competitor for the Director-General's prize for Pathology.

Sir GEORGE WILLIS, after presenting the prizes, addressed the gentlemen whose course of study at Netley had been successfully ended. The General offered them his hearty congratulations, and in the kindest manner gave them some useful hints as to their future career in the service, the result of much experience in peace and war, urging them never to relax their efforts to keep abreast of a constantly advancing profession; reminding them that, like officers in other branches of the service, their efforts in this direction would, under recently published regulations be tested before promotion. Sir George hoped they would cultivate good relations with other branches of the service, by whom their skilful services would be appreciated, and wished them, one and all, a successful and honourable career.

Professor LONGMORE repeated the good wishes and congratulations of himself and his colleagues, and in their name bade them a hearty farewell, declaring the business of the session ended.

The company then adjourned to the handsome mess room of the department, where a sumptuous luncheon was served. Among the guests were some of the officers of two ships of the United States Navy; one the *Lancaster*, bearing the flag of Rear Admiral Nicoll Ludlow

HEALTH IN WORKSHOPS.

ON the 31st ult., Mr. J. B. Lakeman, inspector under the Factory Acts, delivered an address in the lecture-room at the Health Exhibition on this subject. He stated that as a nation this country was very backward in sanitative education, and that the laws of ventilation were sadly neglected by employers of labour. Needle-makers, file-makers, grinders, and moulders suffered in lungs to the extent of 50 per cent., flint-cutters of 80 per cent., grindstone-makers of 40 per cent., cigar-makers of 36 per cent., weavers of 25 per cent. (the fibre of cotton being most injurious), brush-makers of 49 per cent., and hat-makers of 15 per cent. (the dust from cheap hats being more injurious than that from the fine felt). Speaking of the want of ventilation and sanitation in factories, he said that in this category they should exclude textile mills, not generally, but particularly. He advocated, however, that all factories should be placed on the same level, as the law said should be the case. Coming to the trades under the Act of 1867, such as printers, bookbinders, bakers, artificial flower makers, and dyers, Mr. Lakeman mentioned that these industries in many cases were not conducted under proper lines of ventilation, and referred to the great importance of pure air in keeping workers in health, remarking that the conditions of work in closely confined, overcrowded, and ill-ventilated workshops was something unbearable, and the consequences were fatal to robust life. In the course of the address the author described, with the aid of a diagram and practical experiments, what he regarded as a proper system of ventilation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5851 births and 3909 deaths were registered during the week ending the 2nd inst. The annual rate of mortality in these towns, which in the six preceding weeks had increased from 18·7 to 24·9 per 1000, declined last week to 23·3. During the first five weeks of the current quarter the death-rate in these towns averaged 22·8 per 1000, against 23·1, 19·3, and 20·6 in the corresponding periods of 1881, 1882, and 1883. The lowest rates in these towns last week were 12·7 in Huddersfield, 14·5 in Bristol, and 15·2 in Plymouth. The rates in the other towns ranged upwards to 28·7 in Leicester, 28·9 in Liverpool, 31·2 in Norwich, and 34·6 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which in the two preceding weeks had been 1257 and 1246, further fell last week to 1035; these included 689 from diarrhœa, 109 from measles, 76 from whooping-cough, 74 from scarlet fever, 46 from "fever" (principally enteric), 21 from diphtheria, and 18 from small-pox. These diseases caused the lowest death-rates last week in Birkenhead and Huddersfield, and the highest rates in Bolton, Leicester, and Preston. The highest rates of mortality from diarrhœa were recorded in Nottingham, Norwich, Salford, Leicester, and Preston; from measles in Blackburn and Bolton; from whooping-cough in Leeds and Sunderland; from scarlet fever in Sheffield and Cardiff; and from "fever" in Blackburn and Halifax. The 21 deaths from diphtheria in the twenty-eight towns last week included 16 in London. Small-pox caused 17 deaths in Greater London (exclusive of 8 metropolitan cases registered outside Registration London), 2 in Liverpool, 2 in Hull, 2 in Sunderland, and 1 in Sheffield. The number of small-pox patients in the metropolitan asylums hospitals situated in and around London, which had declined from 1368 to 1035 in the three preceding weeks, had further declined to 892 at the end of last week; the number of new cases admitted to these hospitals also fell to 66 last week, from numbers declining from 354 to 105 in the six previous weeks. The Highgate Small-pox Hospital contained 45 patients on Saturday last, 2 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined from 231 to 159 in the four previous weeks, rose last week to 196, and exceeded the corrected average by 17. The causes of 79, or only 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Bristol, and in four other smaller towns. The largest proportions of uncertified deaths were recorded in Oldham, Birkenhead, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·0, 22·8, and 23·3 per 1000 in the three preceding weeks, declined to 20·6 in the week ending the 2nd inst.; and was 2·9 below the mean rate during the same week in the twenty-eight large English towns. The rates last week in the Scotch towns ranged from 13·4 and 14·1 in Perth and Leith, to 22·3 in Paisley and 24·4 in Glasgow. The 498 deaths in the eight towns included 40 which were referred to diarrhœal diseases, 23 to whooping-cough, 16 to measles, 11 to scarlet fever, 3 to "fever," 2 to diphtheria, and not one to small-pox; in all, 95 deaths resulted from these principal zymotic diseases, against 116 and 85 in the two preceding weeks. These 95 deaths were equal to an annual rate of 3·9 per 1000, which was 2·3 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœal diseases, which had been 57 and 43 in the two previous weeks, further declined to 40, but exceeded the number in the corresponding week of last year by 7; they included 21 in Glasgow, 8 in Edinburgh, and 4 in Dundee. The rate of mortality from diarrhœa last week in the Scotch towns did not exceed 1·7 per 1000, against 4·1 in the large English towns. The 23 deaths from whooping-cough slightly exceeded the number in the preceding week, and included 12 in Glasgow, 7 in Edinburgh, and 3 in Greenock. The 16 fatal cases of measles considerably exceeded those registered in recent weeks; 10 occurred in Glasgow and 4 in Dundee. The 11 deaths from scarlet fever, which also showed an increase, included 8 in Glasgow, where all the 3 fatal cases of "fever," as well as the 2 of diphtheria, were also recorded. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 66 and 89 in the two preceding weeks, declined last week to 66, and were 10 below the number returned in the corresponding week of last year. The causes of 76, or more than 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had declined in the three preceding weeks from 22·3 to 19·3 per 1000, rose again to 23·0 in the week ending the 2nd inst. During the first five weeks of the current quarter the death-rate in the city averaged 21·5 per 1000, the rate during the same period being equal to 22·9 in London and 17·3 in Edinburgh. The 155 deaths in Dublin showed an increase of 25 upon the declining numbers in recent weeks, and included 22 which were referred to the principal zymotic diseases, against 24 and 16 in the two preceding weeks; of these, 11 resulted from diarrhœal diseases, 6 from "fever" (typhus, enteric, or simple), 5 from scarlet fever, and not one from small-pox, measles, diphtheria, or whooping-cough. These 22 deaths were equal to an annual rate of 3·3 per 1000, the rate from the same diseases being 6·1 in London and 3·6 in Edinburgh. The 11 deaths from diarrhœal diseases considerably exceeded the numbers in recent weeks; the fatal cases of "fever" also showed an increase, while the 5 deaths referred to scarlet fever corresponded with the numbers in each of the two preceding weeks. Seven inquest cases and 4 deaths from violence were registered in the city last week; and 48 deaths were recorded in public institutions. The deaths of infants showed a marked excess, owing principally to the increased prevalence of summer diarrhœa, while the deaths of elderly persons were fewer than those returned in recent weeks. The causes of 23, or nearly 15 per cent., of the deaths registered during the week were not certified.

PUBLIC HEALH IN SWITZERLAND.

THE Swiss Statistical Bureau has just issued its official return of mortality statistics for the principal towns of Switzerland, relating to the three months ending June last. The return embraces all the Swiss towns having a population exceeding ten thousand persons (fifteen in number), and

Digitized by Google

having an aggregate population of rather less than half a million of persons. The mean annual death-rate during the quarter in these towns was 24·7 per 1000, and was 1·3 below the mean rate in the same towns in the corresponding quarters of the eight years 1876–83. With reference to the recent prevalence of zymotic disease in Switzerland, it may be noted that, excepting only typhoid fever, it showed a decline last quarter, somewhat similar to the decline in the general death-rate. It is necessary, however, to refer to the epidemic of typhoid fever which has recently been so fatal in some parts of the country. The deaths from this disease in the fifteen Swiss towns were 228 in the second quarter of this year, against 64, 41, and 18 in the three preceding corresponding quarters. These 228 deaths were equal to an annual death-rate of 2·0 per 1000 in the Swiss towns, which was six times the rate from "fever" in the twenty-eight English towns during the same period. The epidemic was mainly confined to two centres of infection. In Zurich and its suburbs, with a population of 82,846 persons, the deaths from typhoid fever were 127, equal to 7·3 per 1000; while in Geneva and its suburbs, with a population of 70,765, the fatal cases were 82, and equal to 4·6 per 1000. In the thirteen other towns the deaths from this disease in the three months did not exceed nineteen. Towards the end of June the epidemic of typhoid fever in Geneva and Zurich had almost died out. More recently, however, a recrudescence has occurred in Geneva and its suburbs, and the recorded deaths from this disease, which had been 1 and 3 in the first two weeks of July, further rose to 10 in the third week of that month.

THE SERVICES.

THE COMPOSITION OF MEDICAL BOARDS.

A circular of the Government of India, Military Department, notifies a change in the composition of medical boards for the examination of officers of the Indian service proceeding on furlough on medical certificate, whether within or beyond Indian limits. Under the regulations now superseded, an officer of the Indian service, who can be granted furlough for a longer period than an officer of the British service, had to appear before a local medical board, presided over by an administrative medical officer, at the headquarters of divisions and districts, except in emergent cases, when a special medical board could be convened by the officer commanding the station. It has now been decided that all officers of the Indian service are in future to appear before local medical boards, composed of such officers as are available on the spot, subject to the conditions detailed in section 13 of the Regulations for the Medical Department, Bengal, 1882.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon Randolph Webb, to be Deputy Surgeon-General, vice W. Stewart, M.D., granted retired pay; Brigade Surgeon Richard Chapman Lofthouse, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Albert Stanley Knight Prescott, to be Brigade Surgeon, vice R. O. Hayden, retired upon temporary half-pay; Surgeon-Major John Colahan, M.D., to be Brigade Surgeon, vice R. Webb, promoted; Surgeon-Major Thomas Walsh, to be Brigade Surgeon, vice J. H. Whittaker, granted retired pay; Surgeon-Major David Arthur Leslie, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon.

ADMIRALTY.—Staff Surgeon Alexander Scott has been placed on the retired list of his rank.

The following appointments have been made:—Surgeon George J. Fogerty to Chatham Dockyard; Surgeon James S. Wray to the *Banterer*; Surgeon William M. Rae to the *Mistletoe*; Fleet Surgeon W. J. Eames, additional, to the *President*; and Staff Surgeon T. L. Horner, additional, to the *President*.

RIFLE VOLUNTEERS.—1st Cambridgeshire: John Parkinson Atkinson, Gent., M.D., to be Acting Surgeon.—1st Dumbartonshire: Acting Surgeon James Stevenson, M.B., resigns his appointment.—4th Lancashire: William Mitchell Roocroft, Gent., to be Acting Surgeon.—3rd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry): Surgeons Henry William Livett and William Harford Glover Phelps, M.D., are granted the honorary rank of Surgeon-Major.—1st Stirlingshire: Alexander Duncan Fraser, Gent., M.B., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

CHESELDEN AND LITHOTOMY.

To the Editor of THE LANCET.

SIR,—Although Cheselden has been dead upwards of 130 years, perhaps you may find space in your columns for some extracts from the minutes of meetings of the governors of St. George's Hospital relative to him and the performance of lithotomy. The first surgeons to that hospital were appointed on October 19th, 1733—viz., Amyand and Dickens (serjeant surgeons) and Mr. Wilkie; and on the 22nd Cheselden, then surgeon to St. Thomas's Hospital and lithotomist to the Westminster (then Infirmary) Hospital, was appointed surgeon also, and, as it would appear, solely to perform lithotomy; for at a court of governors held on April 1st, 1737, the minutes state:—"Mr. Cheselden, who had from the foundation of the hospital cut the patients for the stone, now desiring to resign, and proposing that another surgeon be chosen for that operation—resolved, that the thanks of the court be given to Mr. Cheselden for his great care and trouble in and about the operation aforesaid." It was then proposed that a court be called to supply his place, and on April 22nd "the court resolved, on the motion of Mr. Ranby, after proper consideration, that it would be of most advantage to the patients, and more to the credit of the hospital, that one only of the surgeons in ordinary be chosen to succeed him; thereupon Mr. David Middleton was unanimously chosen to succeed him. Mr. Middleton was called in, and accepted the office with thanks." At a court held on April 6th, 1745, "David Middleton, Esq., having informed the court that he desired to resign the particular operation for cutting for the stone, as confined to him, but to perform the same in his turn with the other surgeons of this house—ordered, that the consideration of proper persons to perform that operation be referred to the next court"; and on April 27th "it was ordered that the operation of cutting for the stone be left to such of the surgeons of this hospital as think proper to perform the same." Cæsar Hawkins, so eminent as a lithotomist, had then been ten years surgeon to the hospital. In 1864 I saw at an engraver's a plate of a portrait of Cheselden, and, on asking how it came there, I was informed that it had been sent to be destroyed by a relative who was affronted at the little interest taken by the medical profession in the memory of her ancestor. I requested leave to have an impression taken before the destruction, which was courteously granted me. The copy, taken one hundred and eleven years after the likeness was executed, I presented to the Royal Medical and Chirurgical Society, as well as one of his works containing his own autograph and that of Prout and Brodie. Cheselden was appointed surgeon to the Royal Hospital at Chelsea in 1737, where he died on April 10th, 1752. A handsome tomb was placed over his grave in the burial-ground of that hospital. On visiting it lately I found it fast going to decay: a little cutting of the stone might still preserve some memorial of this eminent surgeon. Next to him is buried Sir Everard Home, also surgeon to this hospital. I am, Sir, your obedient servant,

Savile-row, August 4th, 1884. CHARLES HAWKINS.

P.S.—I have presented to the Royal Medical and Chirurgical Society H. Dekker's "Exercitationes Practicæ," edition 1695. At page 193 there is depicted an operation of removing a crushed calculus. I should like opinions as to what this operation was.

THE CHOLERA.

To the Editor of THE LANCET.

SIR,—The subject of cholera is of perennial moment, but it never was more so, we might say, than at the present juncture, in consequence of its prevalence in France. In reference to a letter published in your current issue by Dr. John Roche, retired list of Her Majesty's Indian Medical Service, it should be noted that the malarial view of its etiology is by no means a novel one, as it was forcibly brought under the notice of the profession by Dr. Scriven, retired list of the Indian Medical Service, as long back as 1866 (*vide*

Digitized by Google

THE LANCET of that year, vol. ii., p. 184, *et seq*); and about twelve years ago I remember reading its revival in the columns of a contemporary medical journal, by Dr. Smith. It was under the assumption of a malarial origin of the malady that quinine was indicated and prescribed by mouth and subcutaneously, but it has signally failed to answer, and that reason alone ought, *pro tanto*, to cast into oblivion a view, or a theory, or whatever else we may call it, which has been found to be erroneous. I need scarcely mention in this connexion the absence—or, at any rate, comparative immunity—of cholera in many malarious regions, not only of India, while at other non-malarious places it rages with considerable virulence. That the malarial theory of the origin of cholera is now exploded cannot be gainsaid. Evidence is not wanting to prove that in healthy (non-malarious) regions, such as in some of the tea plantations in India, cholera has frequently been rife, from being imported, of course, while fevers of an ague type have been conspicuous by their absence. Mr. Vincent Richards, medical officer of emigrants, cites some interesting instances of importation among the coolies (labourers) emigrated to the tea gardens in Assam from foci of infection. (*Indian Medical Gazette*, April and May, 1881; and Jan. 1884.) I cannot understand how or for what reason Dr. Roche attributes to Sir Joseph Fayrer his support of the malarial hypothesis, for *I do* not remember reading anywhere his advocacy of such a view. One of his last utterances on the subject was at the International Medical Congress at Amsterdam recently, and he is then reported to have said that he "felt that after twenty-four years' experience he was totally and absolutely ignorant of the cause of the disease." It is idle to rest on that belief in these days of advance, when the germ theory of disease is making such rapid strides; but while we may be duly indebted to modern workers, we cannot forget former ones in the same field of research, for Mr. C. Macnamara long ago advanced this view of the origin of cholera and its propagation. And subsequently Drs. Lewis and Cunningham have tended to confirm that view, though without succeeding in discovering a particular and characteristic virus of cholera. Concerning the germ theory view and my own observations on cholera in the new-born, Dr. Roche writes:—"The cholera witnessed by Dr. Lucas in new-born children discards at a stroke the fungus theory." Now, I venture to hold that that circumstance, on the contrary, tends to afford a great support to the germ theory view. The cholera virus containing the bacilli would appear to have infected the babes through the maternal and placental circulation before birth in some instances, and in others after birth, through the mammary secretion. The doctrine of evolution is fast throwing aside all notions and dogmas concerning origin *de novo* or spontaneous generation alike of disease as of creatures in the animal and vegetable kingdoms. It is, therefore, hardly tenable, I beg respectfully to observe, to write as he does: "I trust no one believes that cholera or its contagium existed in the Ark as a specific thing; this being granted, it follows that cholera may under extraordinary and exceptional circumstances arise spontaneously." Now, might we question that which is rendered a premise for his argument, what scientific evidence have we that such a thing as the Flood or Deluge took place, and that Noah and his people, his mammals, birds, and reptiles, alone were saved in the Ark?

Dr. Roche says that he is ready to swallow "any amount of Prof. Koch's bacilli, provided they are well washed in distilled water until the colour of the permanganate is slowly affected." As Koch is now exhibiting the bacilli at Paris from cases which occurred at Toulon and Marseilles, Dr. Roche, by proceeding to Paris, will have an opportunity of trying the experiment he refers to. At the same time, I trust he will not undertake so fatal an experiment, and make an untimely call on his friends to mourn their loss.

I am, Sir, yours truly,

Edinburgh, July 21st, 1884. JOHN C. LUCAS.

To the Editor of THE LANCET.

SIR,—A considerable amount of discussion is going on at the present time in France and elsewhere as regards the propagation of cholera by the agency of the air. A residence of several years in India and experience gained in several severe epidemics of that disease must be my apology for asking you to be so good as to insert the following remarks in your valuable journal, as facts coming under my own notice, and proving, I think, that the agency of the air in the diffusion of cholera may sometimes exist as the chief, if not only, factor.

From what is known of the whole life of the lowest organisms, it is undoubted that they possess the faculty of living in the air, as well as when attached to different solid substances, but they lead a much less active life, and their capacity for increase is much diminished outside of fluids; developing, however, dangerous energy when moistened, as seen in the infection of those who had been employed in washing the linen or other articles used by cholera patients. In my own experience, I have seen cholera cases appear simultaneously in various houses and barracks at a station where none existed before, and where none existed within a very great distance from the locality. And not only did these cases appear all within the same hour, usually in the night time, but, taking a line from the house on the outermost part of the station, it was found that the epidemic followed a straight or sometimes a diagonal course through the whole place, as if wafted through the open doors or windows in a current of air, and, seizing its victim or victims, passed on to the next building straight in its direction, leaving those to the right or left untouched, to attack those in the succeeding house. In one instance I saw a cholera epidemic follow the occurrence of a dust storm in India, which broke on the Rock of Gwalior one afternoon in the month of June, 1867, after skirting the cantonment of Morar, some four miles away. It was accompanied by rain and hail, dust and sand, with a high wind, and it passed away as rapidly as it appeared, but directly after its passage cholera broke out, attacking simultaneously the European and native soldiers in the barracks of the fortress on its summit, as also men employed at work on various parts of the Rock. Not a single case of cholera existed either in the town of Gwalior, in Morar, or in any of the villages for a great distance round, nor had done so for a considerable time previously; and I may add that this same phenomenon was observed in 1881 at the same place by the medical officer then in charge of the fortress, confirming what I myself had observed fourteen years before; this can only be put down as an outbreak of the disease occasioned by the transport thither of the cholera germs by the agency of the air, its dangerous qualities being probably heightened by the rain falling at the time.

I am, Sir, yours truly,

W. WAKEFIELD, M.D. Univ. Glasg. & Paris,

July 21st, 1884. Late Army Medical Department.

"THE LOSS OF THE MEDICAL BILL."

To the Editor of THE LANCET.

SIR,—As some victories are hardly distinguishable from defeats, so some apparent losses turn out in the end to be real gains, and among these latter I agree with you in thinking that we must reckon the loss of the Medical Bill. As proposed to be amended (?) by Sir Lyon Playfair, it would have provided for an examining board in each division of the kingdom, to be kept up as a standard of what such boards should be; while at the same time, by the device of appointing coadjutor examiners to university and conjoint board examinations, it would have rendered it unnecessary for a single student to pass the new boards. In at least two divisions of the kingdom it would clearly have been the interest, and probably the desire, of those bodies whose representatives formed the divisional boards to ensure the failure of the new examining boards, while, failure or no failure, the examinations must have continued to be held while the Act remained in force, and the double expense of these and the coadjutor examiners must have come out of the pockets of somebody in the profession or of those just entering it. It would surely have been a great misfortune to have had such a system as this fixed upon us for the next quarter of a century or so, and no pains should, I think, be spared to prevent the possibility of such a calamity occurring next session. Personally I am of opinion that the Government Bill, even without Sir L. Playfair's amendment, was seriously defective in that it attempted too much in one direction and too little in another. I agree with Dr. Farquharson's speech on the second reading, that the Bill would probably have injured, if not ruined, the corporations; and I do not think that in England, at any rate, there is any desire to see these bodies either ruined or seriously injured,

Digitized by Google

nor have I seen any evidence of such desire on the part of the profession in Scotland or Ireland. On the other hand, the Bill touched the radical defect of the Medical Council—i.e., its non-representative character—with such a tender hand that I doubt very much if for practical purposes there would have been a pin to choose between the old Council and the new. At a time when some two millions of uneducated agricultural labourers are about to get votes for the election of representatives in the body which governs the nation, it seems to me a little absurd that it should be offered as a great boon to twenty thousand members of a learned profession that they should have the right to elect less than one-fourth of the body which governs their own profession. Let us go in for a thoroughly representative Council first, and our difficulties in obtaining other necessary reforms will be very much diminished.

I am, Sir, yours truly,

Dulwich, August 2nd, 1884. H. NELSON HARDY.

DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—In your Paris correspondent's letter of July 26th, various experiments by M. Pasteur to determine the efficacy of different disinfectants are recorded.

Some years ago, when I was medical officer of health, I conducted some similar experiments by exposing vaccinia lymph in small chambers to the influence of various disinfectants. The results of these experiments were embodied in my Government report. The disinfectants I used were sulphurous anhydride chlorine, euchlorine, carbolic acid, and sanitas. Owing to the passing of the Cruelty to Animals Act, I had to test the lymph on the babies brought for vaccination; the difficulty in obtaining the consent of the mothers prevented me from carrying the experiments to a satisfactory conclusion, but as far as they went they appeared to point to euchlorine as being by far the most powerful. There are at least two distinct classes of disinfectants: those that kill the microbes (germicides), as corrosive sublimate; and those that destroy or consume the germ by setting free nascent oxygen or ozone. Fresh air, containing as it does free ozone, acts in this way. As each molecule of euchlorine sets free four atoms of oxygen in the nascent condition, thus $Cl_2O_3 + XCl + H_2O = 2HCl + XCl + 4O$, it is probably the most powerful of its class. The free chlorine that it contains doubtless, also, contributes to its efficacy. Euchlorine is a mixture of free chlorine, or chlorine very loosely combined, and chlorous oxide, Cl_2O_3, and is prepared by pouring strong hydrochloric acid on potassium chlorate and applying a gentle heat. I usually placed a small basin containing the chlorate in a large one full of boiling water, and on pouring in the hydrochloric acid the euchlorine was freely given off. The practical experience of several years' use in all cases of fever fully bore out the theoretical experiments, that in euchlorine we have a cheap, simple, and effective disinfectant.

I am, Sir, yours truly,

T. HATFIELD WALKER, L.R.C.P.

Newcastle-on-Tyne, July, 1884.

NORTH LONDON CONSUMPTION HOSPITAL.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an annotation in THE LANCET of July 12th, headed as above. The writer insinuates that the abuses of the last fifteen years are due to a committee over which I have had control.

The facts are: (1) That neither I nor the medical staff have had *any* voice in the management since 1868; (2) that all present attempts at reform owe their origin entirely to the exertions of the medical staff; and (3) that many years ago objection was made to the committee by the physicians *against* the printed addresses of the staff *without effect*. As delegate of the medical staff to the committee of management, I assert without reserve that the printing of the out-patients' letters *without* their addresses will be most satisfactory to every member of the medical staff.

I am, Sir, yours obediently,

GODWIN TIMMS, M.D. Lond.

THE Library of the Obstetrical Society will be closed from August 18th to September 18th

BIRMINGHAM.

(From our own Correspondent.)

QUEEN'S COLLEGE.

THE appointment of a Professor of Anatomy who will give his undivided attention to the duties has given universal satisfaction among the friends of the school. Even those who were at first unwilling to sink vested interests see now that much good is likely to accrue to the College by this arrangement. With three demonstrators, all highly qualified and trained in teaching, the anatomical department ought to be second to none, and able to compete with others where the advantage was formerly theirs.

BIRMINGHAM ASSIZES.

After many years' agitation, much perseverance and considerable energy, the town now enjoys the privilege of a distinct court of assize. The first opening was made on the 4th inst., an awkward day for business purposes, being Bank Holiday. Owing to the absence of a separate court, the assizes were held in the Council-house, which has been fitted up and adapted for the occasion. It cannot be said to be a success from a health point of view, for the ventilation is necessarily defective and the transmission of sound bad, and very trying for those whose attention must be fixed for a length of time on important issues. It is proposed to build new courts, a site having already been marked out; but in these times of trade depression the authorities look askance at any large expenditure of money, or, if wishing to indulge, are reminded of a vigilant body of ratepayers, who view with suspicion any movements in this direction for the present. Still, the new courts must ultimately come as a matter of convenience; and now that Birmingham has the advantage of this important concession, it is but a sequence that adequate provision should be made for the proper transaction of the duties pertaining thereto.

THE NEW EYE HOSPITAL.

The new premises of this charity were opened on the 24th ult. by Lady Leigh, in the presence of a large number of friends and visitors. The large and spacious building was tastefully decorated, and much interest was exhibited in the proceedings. The new hospital has accommodation for 70 in-patients, and room for 200 or 300 out-patients daily, the two departments being kept entirely distinct. The cost of the whole will be about £20,000, of which £5000 was given by one donor. The Eye Hospital has ever stood high in public esteem, and has drawn its patients from a very wide area throughout the Midland Counties. It is hoped, therefore, that the deficiency announced of £4000 will be supplied without resorting to more than earnest appeals to the charitable public, who in this town have always most willingly supported the institutions for the relief of suffering and disease.

UNPARDONABLE STUPIDITY.

The Borough Coroner held an inquest a few days ago on the body of a child, who had met with its death from gross carelessness, in a manner almost incredible in this enlightened age. A woman having attended the Queen's Hospital was supplied with medicine for her ailment. The child of a neighbour in the same court was taken ill, and in the wisdom of the friends it was thought that the mixture prescribed for the woman would do it good; accordingly the unfortunate child was dosed with this, was seized with convulsions and died. The mixture turned out to be iron and strychnine. A more roundabout method of treatment could hardly be conceived, and the result showed how ignorant amateurs base their conclusions upon a very slender and treacherous foundation.

MANCHESTER.

(From our own Correspondent.)

HOSPITAL AMBULANCE.

A FEW months since a resolution was adopted by the Board of the Royal Infirmary to the effect that a horse ambulance should be acquired and worked on the plan adopted in some of the large towns in America and also in

Digitized by Google

Liverpool, whereby serious cases of accident or sudden illness are sent for and removed by the hospital authorities, and the proposed experiment here had been looked forward to with some little interest. At the last monthly meeting of the Board, however, this resolution, on the motion of Sir Joseph Heron, the Town Clerk, was rescinded, and the ambulance will not be obtained, at all events for the present. The chief argument used was that Manchester already is provided with ample provision of a similar character in connexion with the police force, there being no less than seventeen admirably constructed hand ambulances on wheels, kept at the various stations and available at any time, day or night; and on the occasion of the recent railway disaster they rendered most effectual assistance in removing the sufferers from the station to the infirmary.

THE ROYAL INFIRMARY.

The annual meeting of the trustees of the infirmary was held on the 31st ult., when the annual report and statement of accounts were adopted. The latter show that the total income of the infirmary, with its allied institutions the fever hospital, the convalescent hospital, and the lunatic asylum, amounted to £62,027 for the past year. The income exceeded the expenditure at the infirmary, the asylum, and the fever hospital, but at the convalescent hospital the income fell below the expenditure by £1740, so that this institution still continues to be a heavy burden on the infirmary funds. The fever hospital has been unusually full during the past twelve months, due to a somewhat prolonged epidemic of scarlatina, and its resources have been somewhat taxed to provide accommodation for all the cases, and it is in contemplation shortly to extend the buildings there. Some meetings have been recently held to consider the desirability of relieving the infirmary of the responsibility of providing accommodation for the infectious diseases of the city, and of handing over the fever hospital to the health authorities of the corporation, but at the meeting alluded to above it was resolved, on the motion of Dr. Renaud, seconded by Mr. Schuster, "That in the opinion of this meeting it is desirable that the future exclusive control of Monsall Fever Hospital should be retained by the infirmary board, provided that a *modus vivendi* can be arranged with the Corporation of Manchester and the health authorities of the surrounding districts."

At the Salford Fever Hospital the accommodation has also been found to be insufficient, and application is about to be made to the Local Government Board for permission to spend £1000 in extending the Wilton Hospital.

NATIONAL VETERINARY ASSOCIATION.

During last week the second general meeting of the National Veterinary Association was held at Owens College, under the presidency of Mr. Thomas Greaves, F.R.C.V.S. The meeting was well attended by veterinary surgeons from various parts of the country, amongst them being Professor Walley, Dr. Fleming, Professor Williams of Edinburgh, J. McCall of Glasgow, and others. The President, in his opening address, dwelt upon the important part which he hoped the Association was in the future destined to play in raising the tone of the veterinary profession. It was the outcome of the various Veterinary Associations which had sprung up in different places during the past few years, and it was intended to follow in great measure the lines of the British Medical Association. Various papers were read, followed by discussion, many of the subjects having considerable interest for the medical profession, such as "Public Health as affected by Food-supply obtained from Animals," by Dr. McCall. The members dined together at the Grand Hotel, and several members of the medical profession were present as visitors.

At the last meeting of the Board of Guardians the subject of provision for infectious diseases was discussed, and it was suggested that buildings be erected near the wrrk-house sufficient to accommodate at least thirty patients.

THE body of the gentleman who recently died from heart disease on the West Pier, at Brighton, after chasing the man who had stolen his watch, has been identified as that of Mr. Alexander Cunningham Tweedie, aged sixty-two, a surgeon, of Caversham-road, Kentish-town, London. At the inquest held before the Deputy Borough Coroner, a verdict was returned in accordance with the medical testimony.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords, on Tuesday, the Criminals Lunatic Bill was read a second time, and the Cholera Hospitals (Ireland) Bill was read a third time and passed. The report of amendments on the Canal Boats Act (1877) Amendments Bill was brought up and agreed to.

State of the Thames.

Lord Forbes called attention to the condition of the Thames, and recommended that the Aylesbury system should be applied to London sewage. Lord Dalhousie, in reply, observed that the Local Government Board had been calling the attention of the Metropolitan Board to the foul state of the river, and that owing to expensive deodorisation a slight improvement had been effected.

In the House of Commons, on Thursday, Sir J. M'Garel Hogg stated to Mr. A. M'Arthur that several plans for the disposal of the sewage had been considered by the Metropolitan Board, but none had been judged satisfactory.

School Pressure.

On Friday, Mr. Mundella assured Mr. Talbot that the Education Department was satisfied that the new code and the instructions to the inspectors would do all that could be done by the department to prevent over-pressure. The London School Board had put all their pupil teachers on half time, and the provincial School Boards were doing their best. He saw no present necessity for an inquiry into the subject.

Ramleh Barracks.

Lord Hartington, in reply to Mr. Ross, stated that a large amount of sanitary work had been carried out in Ramleh Barracks, and although the sick-rate was high (185 out of 1303), the principal medical officer did not attribute that to the state of the barracks.

The Patent Medicines Stamp Act.

Mr. Childers, in replying to Mr. T. P. O'Connor, said of course the patent medicines stamp was not a Government guarantee of the safety and purity of the medicine; but he was disposed to think that the French practice would, perhaps, be followed with advantage. He had no information that a large number of deaths occurred annually from poisonous patent medicines, nor that the Stamp Act had been condemned by the authoritative organs of the medical profession. He could hold out no hope at present of the repeal of the tax, which brought in £160,000 a year.

Royal Commissions.

Mr. Chamberlain stated that the Royal Commission on Merchant Shipping would not extend its inquiry to the sanitary provision of emigrants. Sir C. Dilke stated that the Royal Commission on Dwellings of the Poor had finished its inquiry as to the condition of rural parts of England and Wales.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — The following gentlemen were admitted Members of the College on July 31st:—

Pitt, George Newton, M.D.Camb., St. Thomas's-street.
Sieley, Richard, M.B.Lond., Park-row.
Younger, Edward George, M.D.Brux., Hanwell.

On the same day the following candidates were admitted Licentiates of the College:—

Airth, George Leslie, M.D.Toronto, St. Peter-street.
Banham, William Wilfred, Worsborough Dale, Barnsley.
Barritt, Gilbert Lacy, Waterside, Todmorden.
Bateman, Fredk. Augustus Newton, Pall-mall.
Beardmore, George Russell, Upper-street.
Beaumont, Edgar, Gipsy-hill.
Bell, James Francis, Vicar's-road.
Biden, Charles Walter, St. Mary's-road.
Bowhay, Albert, Gunnislake, Tavistock.
Brogden, Richard William, The Grove, Clapham-road.
Bronstorph, Ernest Ebenezer, M.D.Montreal, Philpot-street.
Brown, Wm. McEnery, M.D.Toronto, St. Peter-street.
Castor, Richard Henderson, Ainger-road.
Chambers, Herbert William, Lowestoft.
Collins, Arthur Ward, Rainhill, Prescot.
Collins, George William, Adelaide-road.
Collyer, James Ralph, Enfield.
Craddock, Sidney Ernest, Milman-street.

Price, John Dudley, Waddam's Pool, Dudley.
Reilly, Charles Cooper, Denbigh-street.
Roberts, James Reid, Vernon Chambers.
Roberts, Owen William, Cambridge-gardens.
Salvage, John Valentine, Lancaster-road.
Sharp, Charles John, Normanby-place, Liverpool.
Shaw, Harry Charles Costello, Kingston-on-Thames.
Smith, Edward Arnold Cloete, Shooters-hill.
Smith, Howard Lyon, Tellington-park.
Southcombe, Arthur Geo., St. Bartholomew's Hospital.
Stevenson, John, Tachbrook-street.
Stewart, Andrew, M.D. Montreal, Great Coram-street.
Thurston, Hugh Champneys, Nicholas-street.
Trevan, Fredk. Adolphus, Melville Hospital, Chatham.
Trevor, Robert, Halsey-street.
Watkins, Arthur Muriel, Guilford-street.
West, John Arthur, Bickley Park.
Williams, Ezra Herbert, M.D. Toronto, St. Peter's-road.
Wilson, Arthur Henry, Abercromby-square, Liverpool.

COLLEGE EXAMINERS.—The following gentlemen have been appointed Examiners for the ensuing year:—Chemistry and Chemical Physics: Chas. Rumley Alder Wright, D.Sc., Chas. Wm. Heaton, F.I.C., Thomas Stevenson, M.D., Albert James Bernays, Ph.D. Materia Medica, Medical Botany, and Pharmacy: Evan Buchanan Baxter, M.D., Frederick Thomas Roberts, M.D., Thomas Lauder Brunton, M.D., John Mitchell Bruce, M.D. Physiology: William Henry Allchin, M.B., David Ferrier, M.D., Herbert Watney, M.D., John Harley, M.D. Osteology and Anatomy: William Anderson, F.R.C.S., L.R.C.P., Robert E. Carrington, M.D., James Anderson, M.D., Henry Morris, F.R.C.S., L.R.C.P. Medical Anatomy and Principles and Practice of Medicine: Sydney Ringer, M.D., William Howship Dickinson, M.D., William H. Broadbent, M.D., William Selby Church, M.D. Midwifery and Diseases Peculiar to Women: William Smoult Playfair, M.D., John Williams, M.D., John Baptiste Potter, M.D., James Watt Black, M.D. Surgical Anatomy and Principles and Practice of Surgery: Sydney Jones, F.R.C.S., John Couper, F.R.C.S., Alfred Willett, F.R.C.S., Thomas Bryant, F.R.C.S.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 31st ult.:—

Baillie, Robert Alexander, Blackheath.
Blight, William Lyne, Sladesbridge.
Chapman, Harry Cecil, St. Mary's-terrace.
Drew, Arthur John, Gloucester-place.
France, Edward, Sheffield.
Heath, Charles Joseph, Cromwell-road.
Hiddingh, William Henry, Balham.
Maher, Charles H., L.K.Q.C.P.I., Sydney, New South Wales.
Percival, Frank, Leinster-square.
Pinches, William Hooper, L.R.C.P. Edin., Fulham.
Scott, Alfred Langston, L.S.A., Dunmow, Essex.
Smith, J. A. Phin, Granville-square.
Stewart, Arthur Hastings, Colville-terrace.
Tomlins, William Henry, L.S.A., Rutland-street.
Tratman, Frank, Bristol.
Wilkin, Griffith Charles, Hyde-park-street.

Admitted Members of the College on the 1st inst.:—

Arkle, Charles Joseph, L.S.A., West Derby, Liverpool.
Caleb, Clement Cornelius, M.B. Durham, Allahabad.
David, Evan Thomas, L.S.A., Pontypridd.
Gilks, Norton Gilbert, L.S.A., Leominster.
Hill, Rowland, L.S.A., Beeralston.
Kidd, Leonard Joseph, Cambridge-street.
Pring, Frederick Arthur, L.S.A., Exeter.
Wright, William Henry, L.K.Q.C.P.I., Liverpool.

Admitted Members of the College on the 4th inst.:—

Appleton, Harry, L.S.A., Granville-square.
Haw, Walter Herbert, L.S.A., Cape of Good Hope.
Livermore, William L., L.S.A., Finsbury-park.
Marriott, John, L.R.C.P. Lond., Leicester.
Penny, Edmund John, L.S.A., Dorchester.
Sherrington, Charles Scott, L.R.C.P. Lond., Ipswich.
Squire, Walter Perfect, Torquay.

Admitted Members of the College on the 5th inst.:—

Bolton, George Augustus, Surbiton.
Gray, J. P. William, L.S.A., Barnsbury-park.
Guilding, Lansdown Murray, L.S.A., Reading.
Marshall, W. L. Wright, L.S.A., Brixton-rise.
Phillips, Ernest Willmer, L.S.A., Brighton.
Roberts, J. S. Hughes, L.S.A., Swansea.
Wey, Alfred Cox, L.S.A., Plymouth.
Windley, William, L.S.A., Nottingham.

Admitted Members of the College on the 6th inst.:—

Beddoes, Thomas Pugh, Church Stretton.
Cropley, Henry, L.S.A., Swaton, Lincolnshire.
Foot, Ernest George, L.S.A., Bigbury, Devon.
Mackenzie, H. W. Gavin, M.B. Cantab., St. Stephen's-terrace.
Weaver, William George, L.S.A., Hereford.

At the examinations for the diploma of Membership of the College, which have just been brought to a close, St. Bartholomew's sent 53 candidates; University College, 39; Guy's, 27; St. George's, 23; King's College, 19; St. Thomas's, 15; London, 15; Charing-cross, 13; Middlesex, 13; St. Mary's, 12; and Westminster, 11. Of the Provincial schools, Manchester took the lead with 24; Cambridge, 13; Leeds, 11; Birmingham, 8; Bristol, 8; Liverpool, 7; Newcastle, 5; and Sheffield, 3. Edinburgh and Glasgow sent respectively 21 and 4; Dublin, 3; Madras 2; Calcutta 1; Bombay, 1; McGill College, Montreal, 3; Toronto, 2; and Amsterdam, 1.

COLLEGIATE HONOUR.—On Tuesday last the honorary gold medal of the Royal College of Surgeons was unanimously awarded to Sir Erasmus Wilson, Bart., a Fellow and past President of the College, in recognition of his liberal contributions to the Museum, in the endowment of the Pathological Curatorship, and in the foundation of the Professorship with which his name is associated. This medal, which was founded in 1800, has only been awarded on six previous occasions; and, curiously enough, the first to receive it was another of the same name, Professor James Wilson, in 1822. Mr. James Parkinson obtained it in 1825; Mr. Joseph Swan, a former member of the Council, in 1834; Dr. George Bennett, of Sydney, in 1869; Dr. H. L. Crowther; and, in 1876, Dr. F. B. Peacock.

REMOVAL FROM THE MEMBERSHIP.—At a meeting of the Council on the 5th inst. the following resolution was carried unanimously: "That in the opinion of the Council the advertisements and publications issued by Mr. George Washington Evans are, in the terms of clause 2, section xvii. of the Bye-laws, 'prejudicial to the interest,' and 'derogatory to the honour of the College,' and 'disgraceful to the profession of surgery,' and that, in consequence of the issue thereof by him, he be removed from being a Member of the College."

UNIVERSITY OF LONDON.—The following candidates have passed the recent Preliminary Scientific (M.B.) Examinations:—

FIRST DIVISION.—James Cameron (Ph.), Univ. Edin.; John David Cruickshank (Ph.), Guy's Hosp. and private tuition; J. Lacy Firth,* W. J. Hancock,* and J. Sinclair McGowan,* Owens Coll.; E. Hambury Hankin, Frank Spiller Locke, Bedford Pierce, E. Noel Reichast, and John Wilkie,* St. Barthol. Hosp.; Alfred Parkin, Yorkshire Coll.; Ransom Pickard and C. Hubert Roberts, Univ. Coll.

SECOND DIVISION.—C. Francis Abbott,* H. Carpenter Bristowe, W. Macdonald Helsham, F. Maurice House, E. Augustus Roberts, and Reginald Vaughan Solly, St. Thomas's Hosp.; Frederic W. Abbott, Charing-cross Hosp. and private study; J. Hill Abram, Univ. Coll. and Roy. Infirm. School of Medicine, Liverpool; Magnus Adler, private study; Theodore Baker,* F. Richardson Blaxall, A. Wilson Boning, H. G. Graham Cook, C. Seymour Dowdell, H. E. Durham, H. Muir Evans, W. Solteau Fenwick, Hilarion M. Fernando,* R. Foster Gill, Kenneth McLaren, Chandi Charan Sen, Henry Sharman, W. W. Hunt Tate, E. Olive Turner, G. B. Mower White, W. G. Willoughby, Ernest Wills, and Charles Wilson, Univ. Coll.; H. Stanley Ballance* and H. A. Lepthairia Pope, King's Coll.; R. Attwood Beaver, School of Medicine and Univ. Coll., Liverpool; A. J. Bennett, St. Barthol. Hosp. and private study; Annette Matilda Benson (Z.), Newnham Coll., Camb., and private study and tuition; A. E. Berry, F. H. Warburton Cottam, G. E. Fryer (Ph.), T. Ashton Goodfellow, Henry Langdale, Robert Ellis Lord,* Richard H. Read, and Edward Herbert Robinson (Ph.), Owens College; William Jenner Best (Ph.), Cavendish College, Cambridge, and private tuition; Robert Bird, Thomas J. Dyall, Alfred M. Gledden (Ph.), Thomas E. Spencer, and Herbert Williams, St. Barthol. Hosp.; F. Frost Blackman,* private study; Bokenham, Thomas Jessop, St. Barthol. Hosp. and private study; George Goss Borrett,* Harry Corner, W. Thomason Grenfell, A. D. Percival Hodges, Charles R. Killick,* and J. K. Warry, London Hospital; Arthur Boulton, Epsom Coll. and private tuition; Richard Oxley Bowman,* Old Trafford School and Owens Coll.; William Branson,* Firth Coll. and School of Medicine, Sheffield, and private study; James Buchanan and William J. Cameron, Queen's College, Belfast; H. Ambrose Burrowes, Univ. College, Liverpool; C. Mackinnon Clark, St. George's Hospital; J. Hazelwood Clayton, Arthur Gerard Irvine, G. Saint Johnston, Alfred Kingsland, and Harold Mason, Mason Coll., Birmingham; Francis H. Cooke (Ph.), University Coll. and private study; George H. Cooke,* Owens College and private

Digitized by Google

study; Henry Scarborough Cooper,* Westminster Hospital; T. P. Cowen, private study; Abel Davies, Univ. Colls. Aberystwith and Cardiff; Cyril S. Davis, A. Downing Fripp, H. Vigers Hickman, A. Byrn Hudson, G. Lyjus Kemp, W. Job Maillard,* Charles J. Martin,* Albert E. Norburn, and C. Frederic Routh, Guy's Hospital; Bertrand E. Dawson, Univ. Coll. and private tuition; P. Rashleigh Dodwell (Z.), Univ. Coll. and private study; Percy J. Duncan, Ronald T. Graveley, Henry E. Knight, and Sidney B. Smith, Epsom Coll.; Robert H. Elliot, private tuition; Harry W. Elphick,* Epsom and Univ. Colls.; George Sinclair Farquharson, Univ. Coll. and London Hosp.; Fredk. A. Field,* private study; Ernest E. Francis, St. Barthol. Hosp. and private tuition; Gerald Dudley Freer (Ph.), Queen's and Mason Colls., Birmingham; Arthur E. Giles,* Owens College and private study; William Gordon,* Trinity Coll., Cambridge; J. Temperley Grey, Samuel Wolferstan Morgan, and William Taylor (Z.), Univ. Coll., Bristol; John Arthur Hayward, Univ. Coll. and private study; Thomas Johnson,* Normal Sch. of Sci., S. Kensington, and private study; E. Lloyd Jones,* Unattached Camb. Univ.; Harold A. Kidd, St. Mary's Hosp.; Charles R. Lane, Yorkshire Coll., Leeds; Hans H. Mack, London Hosp. and private study; R. Devereux Mothersole, Guy's Hospital and private study; Berkeley G. A. Moynihan, Yorkshire Coll. and Leeds Sch. of Medicine; C. Octavius Parsons, St. Thomas's Hosp. and private study; T. Wilkenee Piper,* St. John's Coll., Battersea, and Univ. Coll.; Cecil Price-Jones, Univ. Coll. and Guy's Hosp.; G. H. Drummond Robinson, private study and tuition; Charles E. Smith, private study and tuition; Daniel Benham Spence, London Hosp. and private study and tuition; Christopher P. Spink, Leeds Med. Sch. and Yorkshire Coll.; Theodore M. Stiles, Bristol Med. Sch. and Univ. Coll.; Sidney S. Swift, Liverpool Roy. Infirm. Sch. of Med.; Herbert J. Thomas, Bristol Med. Sch.; Robert H. Tompsett, Crewkerne Sch. and Univ. Coll.; Francis W. Tunnicliffe, St. Barthol. Hosp. and private tuition; Frederic J. Webb,* Roy. Coll. of Sci., Dublin, and private tuition and study; Joseph Wright, Yorkshire, Coll., Leeds.

CHEMISTRY ONLY.—Launcelot W. Andrews, St. Barthol. Hosp.; John Edwin Wood, B.A., Yorkshire Coll., Leeds.

EXPERIMENTAL PHYSICS ONLY.—George Dines Parker, St. Barthol. Hosp.; Edward Posnett, Yorkshire Coll., Leeds, and private tuition; Robert Ward, Bristol Med. Sch. and private tuition.

BOTANY ONLY.—Henry E. Leigh Canney, Univ. Coll.; David T. Jones, Cyrus Legg, and David Foulkes Roberts, Guy's Hosp.

ZOOLOGY ONLY.—James J. Buist, St. Barthol. Hosp.; E. Delacourt Kell, London International and Univ. Colls.; Thomas Wilson Smith, Guy's Hosp.; Fredk. W. Stokes, Queen's and Mason's Colleges, Birmingham.

* Also passed in the Mathematics of the Intermediate Examination in Science, and have thus become admissible to the B.Sc. Examination.
(Ph.) Postponed their Examination in Physics.
(Z.) Postponed their Examination in Zoology.

UNIVERSITY OF GLASGOW.—The following candidates have obtained the under-mentioned degrees during the summer session, 1884:—

DOCTOR OF MEDICINE.

Allan, Robert, M.B., Scotland.
Boyd, J. Dunlop, M.B., Austral.
Donald, David, M.B., Scotland.
Hargreaves, Mark K., M.B., Eng.
Goff, John, M.B., Scotland.
Lewis, J. Robertson, M.B., Scot.
Middleton, G. S., M.A., M.D., Scot.
Miller, Robert, M.B., Scotland.
Morrison, Wm., M.B., "
Macphee, Angus, M.B., "
Smith, P. C., M.A., M.B., "
Steven, J. L., M.B., "
Thomson, James, M.B., "
Wills, James, M.B., "

BACHELOR OF MEDICINE AND MASTER IN SURGERY.

Auld, Alexander G., Scotland.
Bamber, Harry, "
Beveridge, John, "
‡Blakely, William T., "
Brown, William, "
Brown, William, "
‡Brown, William M., "
Brownlee, John Innes, S. Africa.
Clark, George, Scotland.
Cowie, James, "
Crawford, James, "
Cullen, William, "
Cumming, J. B., South Africa.
Cunningham, John, Scotland.
Dobie, Henry E. N., China.
Ecklin, William, Scotland.
Findlay, James, "
‡Finlay, David, "
Frew, Alexander, "
‡Fulton, Andrew B., "
†Greener, Michael H., England.
*Hawthorne, C. O., "
Hinshelwood, J., M.A., Scotland.
Jack, Alexander, "
Kelly, Hugh, "
Kendall, Francis E., England.
Keogh, Arthur G., Australia.
Kerr, John A., Scotland.
Killoch, Matthew, "
King, Charles G., "
Kirkpatrick, A., "
Livingstone, R. "
Marquis, Duncan, "
Marshall, W. G., M.A., Scotland.
Mason, Henry, England.
Mathie-Morton, J. M., Scotland.
‡Miller, Robert G., "
Montgomery, A. N., "
‡Murdoch, Andrew, "
Murdoch, J. W. A., "
Macarthur, Benj. W., "
Macentrey, D., M.A., Scotland.
M'Cracken, William, "
M'Creadie, William, "
‡M'Culloch, T. C., "
Macdonald, Roderick, "
MacDougall, Alex., "
MacGilvray, Duncan, "
Mackenzie, Ernest, England.
Mackinnon, C., M.A., Scotland.
Mackintosh, D. J., "
Mackphail, Digby M., Jamaica.
Macrae, Alex. M., Scotland.
Paterson, Alexander B., India.
‡Peacock, Alexander, Scotland.
Pretsell, William G., "
Ralley, James, "
Rankin, William, Ireland.
Reddie, John O., Scotland.
Ritchie, John, England.
Robertson, Alexander, Scotland.
Russell, Frank, "
Rutherford, H., M.A., "
Scott, Gavin S., "
‡Scott, Robert, Australia.
Semple, Miller, Scotland.
Service, R. M., "
Sharman, Mark, England.
Shaw, James, Scotland.
Sinclair, John, "
Smith, W. M., "
Somerville, W. F., M.A., Scotld.
Spence, Walter W., "
Taylor, Francis, "
Taylor, William C., Australia.
Thornley, Joseph, England.
Todd, George B., Scotland.
Watt, Allan, "
White, John, "
†Wilson, George, "
‡Wilson, J., M.A., B.Sc., Scotland.

* Honours; gained also the Brunton Memorial Prize of £10, awarded to the most distinguished Medical Graduate of the year (1884).
† High Commendation. ‡ Commendation.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates passed the Final Examination at the July sittings of the Examiners, and were admitted Licentiates of the Faculty:—

Barnett, F. S., Stoke Newington.
Barry, D. M., West Drayton.
Boothman, Alex. C., Glasgow.
Fairley, Saml. B., Birmingham.
Goodwin, A. G., Glasgow.
Jameson, David, Newtonards.
Margesmont, John G., Ceylon.
Taylor, Alfred, Bolton.
Wilkinson, Ernest W. C., Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates passed the recent Final Examination for the double qualification, and were admitted Licentiates of the Faculty and of the College:—

Anderson, John G., Glasgow.
Drysdale, William, "
Forrest, J. S., "
Hallock, S., Edinburgh.
Johnson, O., "
Jones, J., Glasgow.
Jones, W., "
Morgan, Rees, Glasgow.
Necon, J. T., "
Owen, John H. "

BRITISH MEDICAL SERVICE.—The following is a list of Surgeons on Probation in the Medical Department of the British Army who were successful at both the recent London and Netley examinations. The marks shown are those which were gained at the London examination; the order of position of these gentlemen is not affected by the marks gained at the Netley examination:—

	Marks.		Marks.
J. R. Barefoot	2440	J. I. P. Doyle	2145
R. H. Clement	2420	N. Manders	2120
G. D. Hunter	2335	L. R. Colledge	2110
W. C. Beevor	2300	S. F. Freyer	2075
L. E. Anderson	2275	†C. Birt	2070
*G. B. Russell	2250	R. S. F. Henderson	2020
A. E. C. Spence	2220	H. Mitchell	2000
J. R. Mullins	2200	S. Butterworth	1990
R. J. McCormack	2186	C. J. Holmes	1930
H. N. Thompson	2169	I. R. Lane	1920

* Gained the Montefiore second prize.
† Gained the Parkes' Memorial Bronze Medal.

INDIAN MEDICAL SERVICE.—The following is a list of Surgeons on Probation in this service who were successful at both the London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown below:—

	Marks.		Marks
*J. H. T. Walsh	5517	G. H. Fink	4423
†H. Hendley	4879	W. G. P. Alpin	4146
H. E. Banatvala	4696		

* Gained the Herbert Prize of £20, with the Montefiore Medal and Prize of 20 guineas, and the Martin Memorial Gold Medal.
† Gained the Director-General's Prize in Pathology.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 31st:—

Brookfield, Samuel, Dresden, Staffordshire.
Carrington, William Henry, St. Thomas's-street.
Fowler, Thomas Webb, Summer-lane, Birmingham.
Hall, Gilbert Capel, Bath-row, Birmingham.
Haw, Walter Herbert, Mecklenburgh-street.
Lane, Frank, Bedford-road, Tottenham.
Marshall, William Lawrence Wright, Brixton-rise.
Pinniger, Charles Lever, Bennett-park, Blackheath.
Wright, Frank Marsh, Bottesford, Nottingham.

The following gentleman also on the same day passed the Primary Professional Examination:—

Lavies, Harry Brandreth, King's College Hospital.

GUY'S HOSPITAL.—The Library of this Hospital will be closed on Monday, August 11th, and reopened on Monday, September 1st.

UNIVERSITY OF EDINBURGH.—In the Edinburgh University pass list, as published last week, the name "J. D. Davies," should have been D. Davies Jones.

MR. SAMUEL MORLEY, M.P., President of the London Temperance Hospital, has forwarded to the funds of that institution a donation of £500.

NEW MAGISTRATE.—Mr. T. H. Bartleet, F.R.C.S., has been placed on the Commission of the Peace, and qualified last Monday at the opening of the first Birmingham Assizes.

ON the 31st ult., at Chelmsford, one of "the Peculiar People" was found guilty of the manslaughter of his daughter by neglecting to call in medical aid in an illness from which she died, and sentenced to one month's imprisonment.

Digitized by Google

PRIZES FOR SURGICAL ESSAYS.—The Medico-Surgical Society of Bologna has offered two prizes of 500 lires each. The first prize is for the best essay on "The Surgical Treatment of Pulmonary Cavities"; the subject for the second prize is, "The Surgery of Diseases of the Stomach." The essays must be written in Italian, French, or Latin.

THE JAFFRAY HOSPITAL.—At a meeting of the Committee of the Birmingham General Hospital, held last week, a letter was read from Mr. Jaffray, offering to devote, for the purposes of the Jaffray Suburban Hospital, four acres of land, in addition to the site already given by him. The gift was accepted with thanks.

STATE OF THE THAMES.—On the 2nd inst. a committee of the Metropolitan Board of Works inspected the Thames at Woolwich, and were gratified to find that the measures of deodorisation of the metropolitan sewage recently adopted at the outfalls have proved successful. The water presented its normal appearance, and there were no offensive smells on the banks or on the stream.

SUICIDE OF A MEDICAL MAN.—The Liverpool papers announce the death, by the inhalation of chloroform, of Dr. G. J. Jones, at Adelaide. The deceased was found, on the morning of June 22nd, in bed with a piece of sponge which had contained chloroform pressed against his nostrils, and quite dead. Letters in the room showed that the cause of death was not accidental.

APOTHECARIES' HALL OF IRELAND.—The following have been elected office-bearers for the ensuing year:—Governor: Thomas Collins. Deputy Governor: Robert Montgomery. Court of Directors and Examiners: E. A. Bolland, John Evans, A. Harvey, Charles Holmes, Charles H. Leet, C. F. Moore, H. P. Nolan, R. G. O'Flaherty, E. J. O'Neill, Sir G. B. Owens, John Ryan, James Shaw, and George Wyse. Representative on the General Medical Council: T. Collins.

THE IRISH GRADUATES' ASSOCIATION.—The annual meeting of this Association was held on the 30th ult. in the Queen's College, Belfast, presided over by Prof. William Stokes, of Dublin. A vote of thanks was passed to Dr. Yeo, late President; and Prof. Foster, of Birmingham, was unanimously selected as President for next year. Dr. Frazer, having resigned as hon. secretary, has been replaced by Dr. James Stewart, of Clifton. In the evening the annual dinner was held, which was well attended.

THE SANITARY INSTITUTE OF GREAT BRITAIN.—The autumn congress, 1884, will assemble at Dublin from September 30th to October 4th, 1884. The exhibition of sanitary apparatus and appliances in connexion with the congress will be held in the Royal Dublin Society's Buildings, Ball's-bridge, and will be open from September 30th to October 18th. In addition to the opening address by Sir R. Rawlinson, addresses will be given by Dr. T. W. Grimshaw, Mr. C. P. Cotton, Dr. Alfred Carpenter, and Dr. C. A. Cameron.

CITY PROVIDENT DISPENSARY.—The seventh annual meeting of the governors of this institution was held on the 31st ult. The attendances at the dispensary since July, 1877, has been over 19,300, while the home visits have amounted to close on 1500. In the surgical appliance branch, with regard to which no letter of recommendation is required, and no charge for surgical advice made, nearly 4800 instruments have been supplied since the institution of the Society. It appeared that at the commencement of last month the institution was about £300 in debt.

THE LATE MR. CÆSAR HAWKINS.—At the meeting of the weekly board of St. George's Hospital on July 23rd, 1884, the death of Mr. Cæsar Hawkins having been reported by the secretary, the following resolution was unanimously adopted:—"The weekly board of St. George's Hospital beg to express to Mrs. Cæsar Hawkins their sincere sympathy with her on the loss of her husband. The governors of St. George's Hospital, with feelings of gratitude for Mr. Cæsar Hawkins' eminent services, during a period of fifty-five years, as surgeon, teacher, and trustee, feel confident that the institution, in whose interests he worked for so many years, will continue to profit by an association with his character and name, whilst the public has the advantage of there being a large number of medical practitioners educated by him, and the medical profession by the example of his life, exhibited, as it was, in great scientific and intellectual qualifications, ever accompanied by a highly honourable and most gentleman-like bearing."

METROPOLITAN SEWAGE DISCHARGE.—The members of the Royal Commission on Metropolitan Sewage Discharge met on Thursday, and proceeded to inspect the river in a steamer placed at their disposal by the Thames Conservancy. They embarked at Gravesend at noon, and went below the Nore, returning to Woolwich in the evening, where they landed. The inspection lasted seven hours. There were present Lord Bramwell, Colonel C. B. Ewart, R.E., Dr. F. de Chaumont, Mr. Thomas Stevenson, M.D., and Mr. James Abernethy, F.R.S.E.

BOLINGBROKE HOUSE PAY HOSPITAL.—At a special meeting of the managing committee of this hospital held on August 2nd, it was resolved to open its wards and private rooms for patients sent in under the care of any registered medical practitioner. Hitherto the patients have been attended by an honorary visiting staff, who have given for three years past a constant and efficient attendance at the hospital. At the meeting referred to these gentlemen very kindly facilitated the trial of the new experiment by placing their resignation in the hands of the managing committee.

EPSOM COLLEGE.—The annual distribution of prizes to the students of this college, commonly known as Founders' Day, took place on the 30th ult. After the distribution of prizes by Sir Joseph Fayrer, the head master announced that the governors of St. Mary's Hospital had decided to offer a scholarship of the value of 100 guineas for competition among the students of Epsom College, who must be sons of medical men. The hospital staff of St. Thomas's have also decided to offer a free scholarship to the pupils in the College who had passed either in the first class or in honours at the Preliminary Scientific M.D. at London University.

AMBULANCE INSPECTION.—The inspection of the Ambulance Company of the Tower Hamlets Rifle Brigade took place at the head-quarters, Shaftesbury-street, on August 2nd, the inspecting officer being Surgeon W. E. Webb, M.B., A.M.D. The company was commanded by Surgeon Platt, assisted by Acting Surgeons White and Waterhouse, and consisted of a sergeant instructor and sixteen rank and file; making four stretcher detachments. The various movements incidental to stretcher drill were creditably carried out, and at the termination of the parade, Surgeon Webb expressed his gratification at the manner in which the drill had been executed, and also of the efficiency and intelligence which the bearers had displayed in applying the different dressings.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ADAMS, GEORGE, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Bedminster Rural Sanitary District.

ASHE, WILLIAM CONYNGHAM, L.R.C.S.I., has been appointed Honorary Surgeon to the Newcastle Infirmary, New South Wales.

BARLING, HARRY GILBERT, M.B.Lond., F.R.C.S Eng., has been appointed Demonstrator of Anatomy to Queen's Hospital, Birmingham.

BARON, BARCLAY J., M.B., C.M., has been appointed Physician to the Bristol General Hospital, vice G. F. Burder, M.D., F.R.C.P., resigned.

BIDEN, CHARLES W., M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Children's Hospital, Paddington-green, vice F. T. Hebb, M.R.C.S., resigned.

BIRCH, DE BURGH, M.D., F.R.S.E., has been appointed Professor of Physiology in the Yorkshire College, Leeds.

BLUMER, F. MILNES, B.A.Dunelm, M.B., C.M.Ed., has been appointed Assistant House-Surgeon to the Cumberland Infirmary, Carlisle, vice H. H. Brown, M.B., C.M., resigned.

BURDER, GEORGE FORSTER, M.D.Aber., F.R.C.P.Lond., M.R.C.S., has been appointed Consulting-Physician to the Bristol General Hospital.

BURROWS, C. W. GRIMES, M.R.C.S., L.S.A.Lond., has been appointed Public Vaccinator for the Thornhill District of the Dewsbury Union.

DUTTON, WILLIAM HENRY, M.B., M.Ch.Ed., M.R.C.S., has been appointed Resident Medical Officer to the Castlemaine Hospital, Victoria.

EATON, JOSEPH, M.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Rathcoole Dispensary, vice McEvoy, resigned.

EMINSON, LUTHER, L.F.P.S.Glasg., L.S.A.Lond., has been appointed Medical Officer for the Haxey District of the Gainsborough Union.

Digitized by Google

FOX, FORTESCUE, M.B.Lond., M.R.C.S. (late House-Physician at the London Hospital), has been appointed by the Duchess of Sutherland Resident Physician at the Strathpeffer Spa, Ross-shire, N.B.

FOX, GEORGE, L.R.C.P.Ed., M.R.C.S., has been appointed Resident Medical Officer to the Sydney Hospital.

HADDEN, WALTER BAUGH, M.D.Lond., M.R.C.P., has been appointed Physician to the Royal Hospital for Children and Women.

HASLAM, WILLIAM FREDERICK, F.R.C.S.Eng., L.S.A.Lond., has been appointed Demonstrator of Anatomy to Queen's College, Birmingham.

HUDSON, T. J., M.D., L.R.C.P.Lond., has been appointed Medical Examiner to the Wesleyan and General Assurance Company, and to the Pearl Life Assurance Company, Leeds District.

HUMPHRY, LAURENCE, M.A., M.B.Camb., M.R.C.S., has been appointed Assistant-Physician to Addenbrooke's Hospital, Cambridge.

LEY, HENRY J., M.B. & C.M.Ed., M.R.C.S., has been appointed Resident Surgeon to the Birmingham General Dispensary.

LLOYD, G. JORDAN, M.B., M.S.Durh., F.R.C.S.Eng., has been appointed Demonstrator of Anatomy to the Queen's Hospital, Birmingham.

LOFTHOUSE, ARTHUR, M.R.C.S. & L.S.A.Lond., has been appointed Assistant Medical Officer to the County Lunatic Asylum, Snenton, Nottingham.

MACALISTER, DONALD, M.A., M.B.Camb., M.R.C.P.Lond., has been appointed Physician to Addenbrooke's Hospital, Cambridge, vice Dr. Paget, resigned.

PITT, GEORGE NEWTON, M.A., M.D.Cantab., M.R.C.P., has been appointed Assistant-Physician to the East London Hospital for Children and Dispensary for Women, Shadwell, E., vice Francis Warner, M.D.Lond., F.R.C.P., resigned.

SOUTER, JOHN CLEMENT, M.D., Ch.M.Aber., has been appointed Government Medical Officer and Vaccinator for the District of Gulgong, New South Wales.

SPROULLE, H. MAGINNISS, M.B., B.Ch.Dub., has been appointed Public Vaccinator for the Mirfield District of the Dewsbury Union.

STRUGNELL, WALTER T., M.R.C.S., L.S.A.Lond., has been appointed Senior House-Surgeon to the Metropolitan Free Hospital, vice A. S. Nance, resigned.

Births, Marriages, and Deaths.

BIRTHS.

COUPLAND.—On the 2nd inst., at Weymouth-street, Portland-place, the wife of Sidney Coupland, M.D., F.R.C.P., of a son.

HUNT.—On the 4th inst., at Palace-gardens-terrace, the wife of Bertram Hunt, M.B. Univ. Coll., Oxford, of a son.

SHAPTER.—On the 29th ult., at Barnfield-crescent, Exeter, the wife of Lewis Shapter, M.D., of a daughter.

YOUNG.—On the 30th ult., at Rose-bank, Merton-road, Bootle, the wife of T. F. Young, L.K.Q.C.P.I., M.R.C.S., of a son.

MARRIAGES.

ATKINSON—CHASE.—On the 30th ult., at Kenilworth, Miles Christopher Atkinson, M.D., son of the Rev. J. C. Atkinson, Vicar of Danby, Yorkshire, to Annie Hale Chase, youngest daughter of T. A. N. Chase, Esq., Madras Civil Service (retired), of Avon Lodge, Milverton, Warwickshire.

CANTLIE—BROWN.—On the 30th ult., at St. Martin's Church, Trafalgar-square, James Cantlie, M.A., M.B., F.R.C.S., of Charing-cross Hospital, to Mabel, eldest daughter of Robert Barclay Brown, of Barnes, Surrey.

NEALE—THOMSON.—On the 28th ult., at Edinburgh, J. Headley Neale, M.B., of London-road, Leicester, to Carrie, youngest daughter of the late Captain John Thomson, H.E.I.C.S., of Cromarty, N.B., and granddaughter of the late Rev. John Thomson, of Duddingston Manse, Midlothian.

PARDINGTON—DICK.—On the 2nd inst., at St. Mary's, Putney, by the Hon. and Rev. Robert Henley, George Lucas Pardington, M.D., eldest son of George Pardington, of The Moor, Hereford, to Elizabeth Jessie, eldest daughter of William Bruce Dick, of Carlton House, Putney-hill, S.W.

TWEEDY—POTTINGER.—On the 5th inst., at St. John's Church, Forest-hill, by the Rev. William Martin, George Alfred Tweedy, Bengal Civil Service, to Margaret, second daughter of Dr. R. Pottinger, R.N., Inspector-General of Hospitals and Fleets.

DEATHS.

GREGORY.—On the 1st inst., at Northernhay-place, Exeter, Bradley Gregory, Fleet Surgeon, R.N. (retired), aged 47.

JENKINS.—On the 31st ult., at Fawley, Hants, Robert Walker Jenkins, M.R.C.S. & L.S.A.Lond., Medical Officer of Health for the New Forest Rural District, formerly of Philpot-lane and Charlotte-street, Bedford-square, London.

MARSHALL.—On the 31st ult., at Tisbury-road, West Brighton, George Henry Marshall, M.D., F.R.C.S., late of Birmingham, and Kington, Herefordshire, in his 71st year.

RENTON.—On the 31st ult., at Rothesay-place, Edinburgh, Robert Renton, M.D., F.R.C.P.E., in his 91st year.

STEWART.—On the 4th inst., at Brunswick-terrace, Pendleton, Florence, the dearly loved wife of Alexander Stewart, M.D., and youngest daughter of the late John Shaw, M.R.C.S., of Attercliffe, Sheffield, aged 30.

TWEEDIE.—On the 4th inst., at Brighton, suddenly, Alexander Cunningham Tweedie, Surgeon (late of Galashiels, N.B.), in his 61st year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A HEALTH RESORT IN PRE-TUBERCULAR PHTHISIS.

KLOSTERS in the Grisons is strongly recommended by our Swiss contemporary *Gesundheit* in cases of phthisis, especially in the pre-tubercular stage. It lies 1200 metres (4000 Swiss feet) above the sea-level, and is already well known for its coolness in summer, and for its advantages as a station for the Alpine tourist. In the neighbourhood of the Silvretta glacier expands the mighty mountain landscape in which, protected against the north wind, and luxuriating in the most verdant vegetation, Klosters, with its pure, exhilarating, restorative air, offers peculiar attractions to the convalescent, and particularly to the incipient phthisical. As a "Vorstation" for Davos-am-plats and the Upper Engadine it is coming into peculiar favour.

THE subject of *Dr. Nixon's* paper is treated in our present number.

PNEUMONIC HEMIPLEGIA.

To the Editor of THE LANCET.

SIR,—In connexion with the case of Pneumonic Hemiplegia reported in THE LANCET of May 10th, you may, perhaps, think the following case worthy of notice in your journal:—An elderly lady had been under my care for some time, suffering from chronic bronchitis, accompanied with great debility. Suddenly pain seized her in the left side, and coincidentally the temperature rose about two degrees and a half. On examination pneumonia of a limited portion of the left lung was noticed. Three days after a mitral systolic murmur became clearly audible. Shortly after this she was taken with dizziness, fixed eyes, and all the symptoms of an apoplectic seizure. The mouth was drawn to the right, and there was paralysis of the left side of the body, with muffled and indistinct speech. At the time of the fit the apex murmur had become very loud. The patient, under the most careful nursing, speedily rallied from the stroke, the left leg quickly regained its motor power, the left arm remaining helpless somewhat longer. She was improving very satisfactorily, when suddenly her breathing became rapid, and the systolic apex murmur, which had become all but inaudible, again became very loud. From this time, which was about six weeks after the convalescence commenced, she slowly sank, although she rallied occasionally for a short time under the treatment. A few days before her death she suddenly became speechless, and lost all power over the tongue; there was no loss of sensation or motion in any other part of the body. The murmur at the apex continued very loud quite up to the last.

I am, Sir, yours faithfully,

Street, Somerset, Aug. 6th, 1884. ARTHUR CLARKE.

E. M.—The work could no doubt be obtained through Messrs. Sampson Low and Co., Fleet-street.

J. C. L.—It would serve no useful purpose to revive the controversy.

Digitized by Google

Enquirer.—The Government Education Code for 1883 and 1884 requires the minimum space allotted to each child to be eighty cubic feet. A room 25 ft. long, 16 ft. broad, and 10 ft. high would afford the minimum space for fifty children; but this amount we think insufficient. The minimum space to each child should be 110 cubic feet, with a considerable roof area above the calculated space when practicable; otherwise the atmosphere is apt to become stuffy. A room 30 ft. long, 20 ft. broad, and 15 ft. high to the ceiling or roof-plate would be a suitable size for fifty children, and the air of this should be constantly changed by efficient cross ventilation.

L.R.C.S.E. has not enclosed his card.

CHOLERA AND THE THAMES.

To the Editor of THE LANCET.

SIR,—The indifference of the public to a matter of such vital importance as the disposal and utilisation of the vast sewage of London has long been a source of profound astonishment to me. I am glad to see that at last the very serious question of reform in this particular is being discussed in the columns of the press. Rather more than a year ago, after considerable difficulty in obtaining any information on the subject, I wrote to the press calling attention to the state of the Thames, advocating a change, and recommending, as the best I could hear of M. Liernur's separate system, although I was aware of the many objections attached to it. Some little time later appeared a full report in a London paper of a visit paid by the Lord Mayor and Corporation of London to the Aylesbury works of the A B C Company. From the satisfactory nature of this report it seemed to me as if no further difficulty could exist with regard to the sewage question. The company undertakes to deal with the sewage at the outfall, and there, by a series of chemical processes, convert it into a dry, portable, inodorous guano form of manure, leaving an effluent so harmless that fish live comfortably in it, and so palatable that an adventurous alderman, tasting it at the visit referred to, pronounced it very little inferior to ordinary drinking water. Now, what possible objection can there be to disposing of the filth in the Thames by these clean, simple, and effectual processes? On the threshold of inquiry I am met by a portentous Cerberus—the question of expense. An extended sale of the native guano would be necessary to render the affair self-supporting, and I hear the British farmer, entrenched behind his usual barricade of prejudice, refuses to accept the new manufacture even as a gift, or to apply it to his fields! Remembering the active hostility of some, and the passive, incredulous disgust of others, which attended my late father's earliest use of Peruvian guano, it would be unwise to expect in the present comatose state of the agricultural interest a prosperous fate for any new, or suggestion of a new, remedy, especially at a time when a theory of leaving weeds in possession is cheerfully accepted on the assumption that they retain valuable nitrates which would be lost under a system of rapid cropping and deep cultivation. Happy Liebig! who did not live to hear the virtues of twitch, landbine, and thistles recounted and believed in. How long agriculture will remain in its present condition of semi-paralysis time alone must show; but I fear it will also show the creeping evil extending to every other branch of industry, and to the individual welfare of every member of the community. Upon the prosperous state of agriculture depends the entire prosperity of the nation. Since, however, agriculture can, or will, give no support to the A B C Company in removing from the midst of London its festering mass of inconceivable filth and peril, would not the Londoners allow a modest rate to be levied on them for the purpose? By paying heavy rates for new bridges, handsome streets, and improved systems of lighting, and at the same time neglecting to attend to the disposal of their sewage, the Londoners are in the position of householders who crowd their rooms with elegant and expensive furniture, while allowing the kitchen sink to overflow and poison the whole family. The expedient of throwing chloride of lime into the Thames to deodorise the daily accumulating fifteen to eighteen feet of sewage mud, for all the permanent effect it is likely to have, reminds one of Sidney Smith's story of the child who, when stroking the turtle and asked what she was doing it for, replied, "To please the turtle." "My dear," answered the humourist, "you might as well stroke the dome of St. Paul's to tickle the dean and chapter." I suppose there is nothing for it but to wait until some enormous sacrifice of life and property convinces the authorities that evaded duties and neglected responsibilities return with annihilating force upon those who, from indolence and short-sightedness, sit down passively or obstructively in the presence of evils demanding immediate redress.—I am, Sir, yours faithfully,

Earl's Colne, Essex, July 22nd, 1884. ISABELLA MECHI.

Dr. M. F. Gavin.—The book could no doubt be obtained through Mr. Nock, Bloomsbury-street, London, W.C.

PREVENTION OF "HARVEST BUMPS."

To the Editor of THE LANCET.

SIR,—Children during this hot weather seem terribly troubled with the attacks of the acarus autumnalis. "Harvest bumps" are omnipresent, and restful nights become impossible. Can you or any medical brother suggest any efficient means of preventing these attacks, which reduce so much the enjoyment by our little people of their healthful out-door summer life?—Yours faithfully,

CORNELIUS B. FOX, M.D., F.R.C.P.

Rosemount, Ilfracombe, Aug. 5th, 1884.

INHERITED SENTIMENT.

PROFESSOR SEELEY, in an article on "Goethe," published in the August number of the *Contemporary Review* offers the following interesting remarks on the subject of inherited sentiment:—"Some of those who watched Rossetti at his work thought they discovered that he did not regard his own imaginations seriously . . . . Similarly, Mr. James remarks of Hawthorne that it would be a great mistake to infer from the constant recurrence in his romances of the ideas of sin, retribution, and the stricken conscience, that Hawthorne himself was under the influence of such sombre ideas, the truth being that he was an easy-going, contented, and comfortable man. But Hawthorne's puritanic ancestors took these ideas seriously, and Rossetti's Italian ancestors in like manner furnished the beliefs which in their secondary form suggested Rossetti's pictures and poems. Of all artists, it is Scott who is richest in this kind of inherited sentiment. The shrewd, good-natured, somewhat worldly Scotch lawyer lives in a world of grandiose thoughts, opinions, sentiments, and convictions, out of which he composes at his ease a whole literature; and yet if you ask him what he thinks of these thoughts, opinions, sentiments, and convictions, he can only smile and evade the question. 'Superstition,' he says candidly, 'is very picturesque, and I make it at times stand me in good stead, but I never allow it to interfere with interest or convenience.' They were serious enough to his ancestors, these ideas of clannish devotion, of chivalry, of witchcraft and demonology; but to him they have come simply by inheritance. All he knows is that when he unlocks the ample chambers of his imagination he finds them there; that they work up into capital stories, if hardly fit for practical use; that, in short, they are the old furniture of the house in which Nature has placed him."

Mr. T. William Hughes.—We can see no valid reason for our correspondent not charging.

"GOING TO THE WASH."

To the Editor of THE LANCET.

SIR,—While, as a matter of course, you will agree that cleanliness is an important part of preventive medicine, you will no doubt as readily admit that the earlier in the week the humble housewife gets through her wash, and the sooner her richer neighbour who can afford to "put out" everything sends the soiled linen of the household away, the better will it be for the health of the families concerned. Now, as travellers through the suburbs of London are aware, the laundrymen and women make Monday their grand collecting-day for soiled linen, and many of them send round properly appointed carts and vans. But there is another, and perhaps larger, class of laundry people who cannot, or do not, use conveyances for this purpose, but who send girls or women (mostly to fetch the bundles and baskets. Naturally enough, when long distances have to be traversed by these women, they avail themselves of the cheap rides to be had from point to point by 'bus, rail, or tram-car, and, no doubt with a view to the safe custody of their burdens, they take them inside the vehicle, whatever it is. The atmosphere of our crowded public conveyances is always sufficiently offensive without further contamination by the odours of foul linen, which in warm, wet, and muggy weather are very perceptible. I have on one or two occasions "made myself so disagreeable" as to protest against the conveyance of bundles of dirty linen in omnibuses; and perhaps, if you will again ventilate the subject (for I believe you have done so on previous occasions), it will stimulate others to take exception to the practice. The London General Omnibus Company and the tramway companies should give strict orders to their servants against the practice, which I am sure you will condemn most strongly. To say nothing of the offensive smell of the linen cast by people in good health, who is to say what amount of infection is spread by the presence in the bundles of which I complain of bed or body linen which has been in contact with a fever or small-pox patient

The importance of this subject must be my excuse for troubling you with this letter. I am, Sir, yours faithfully,

L. J. DESSURNE.

London Central Club, New Bridge-street, E.C., July 29th, 1884.

Miss Bromley.—Nothing would be gained by publishing the letter. The views of the public on the question do not coincide with those of the medical profession.

L.R.C.S.E.—Yes, undoubtedly.

Mr. John E. Howe, M.B.—The paper will be inserted in an early number.

PRICKLY HEAT.

To the Editor of THE LANCET.

SIR,—Referring to Mr. Wharton's article in the current number of THE LANCET on "Prickly Heat," I may remark that in a recent voyage to the East several cases of this affection came under my notice. I found that warm applications of bicarbonate of soda with a small quantity each of carbolic and hydrocyanic acids gave speedy relief in every case. My first cases were treated with cold applications; but on one occasion, having used hot water, which happened to be more handy, for the solution, I was much struck with the speedy relief afforded, and employed it in each subsequent case.—Yours faithfully,

Austin Friars, E.C., Aug. 2nd, 1884. KENNETH MILLICAN.

O. S. W.—It is usual to get a fee of a guinea for certifying as to the mental condition of a pauper. Whether or not in the present case our correspondent's services must go unremunerated depends upon the terms of the contract, which is not before us. He cannot be compelled to give evidence without subpœna, or having been bound over to appear at an adjourned hearing of a case. If summoned, he must give evidence as to facts, even if a fee is not paid in advance.

Prudentia.—The list can be taken as only a rough indication of the number of practitioners in the colony.

Mr. Frank Taylor.—*Berliner Klinische Wochenschrift* and *Progrès Médical*.

Progrès is referred to THE LANCET of June 14th, p. 1106.

"INFANTILE DISEASE AND MORTALITY."

To the Editor of THE LANCET.

SIR,—I think the letter of Mr. Tomkins deserves more than passing reference. The evil that he points out is one of national importance, and one that demands the utmost effort of every medical man, by his advice, to lessen. The public look to us for guidance in such matters; and if we were, in our relations to mothers, expectant and otherwise, to impress upon them the dangers of improper management of the infant in its early days, I question whether eventually the death-rate in infant life would not be very much lessened. To show the frightful mortality in early life, let us take the total death-rate (say) for 1882. In the whole of England and Wales during that year 516,813 died, and out of that number 125,147 were infants under the age of one year! Here is a slaughter of the innocents that would have delighted the heart of Herod or Attila, one-fourth of all the deaths occurring in the first twelve months of life. Imagine such a mortality among sheep or cattle. What preventive legislation there would be, to be sure! If the mortality continued at this pace, the duration of human life would be about five years on the average; but happily it does not, for fewer die in the next four years of existence than in the first one.

Now, what are the causes of this frightful infant sacrifice? The greatest undoubtedly are dry-nursing and improper food. Dr. Zoul, coroner for New York, says that "if one hundred infants are put out to dry-nurse, and every care taken, in less than three months seventy will be dead." If this be so, and I believe it is, here is the prolific cause; and until mothers are taught that there is no proper food for their offspring until the period of teething has commenced save their own milk, so will it continue. There is no more difficult task than rearing healthy children on artificial food; it is not too much to say that it is impossible. The evil of dry-nursing their infants has spread from the upper to the lowest strata of society; the feeding-bottle has been the curse of this generation, and it has been the means of bringing out hundreds of patent foods, every one of which is utterly unsuitable for the purpose it is advertised for—an additional evil. We all know that an infant cannot digest anything but milk; and still we see our patients daily dosing them with pap, gruel, bread, &c., when they are a few days old, and thinking this is the correct thing. "Dirty bottles, sour decomposing milk, bread, pap, gruel, soothing syrups, indigestion, malnutrition, and death" might truly be the epitaph written over the untimely grave of many a poor atom of humanity. The dangers of over-suckling are a very trivial affair, and where one child dies from that cause five hundred die from the other.

Personally, I cannot blame myself for being lax in my advice to mothers, and I have even taken the trouble to write a shilling book[1] to teach them how to feed their little ones. But unless every medical man does his share in such a merciful work the mortality will continue, and a coming generation of rickety, consumptive, ill-nourished children will rise up in judgment against us. Must we go to the brute creation for lessons? Does the young calf eat hay, or the bitch feed its offspring on meat? Nature and instinct are the truest guides; and if the dictates of fashion and prejudice are allowed to warp maternal duties and feelings, the curse will surely follow.

I am, Sir, yours truly,

Aug. 4th, 1884. NATHANIEL EDWARD DAVIES.

Mr. J. Holdrich Williamson, M.R.C.S.—The letter scarcely calls for notice at our hands.

T. E. B.—"under the circumstances," must excuse us from replying to his query.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—Will you permit me to correct a slight error in your account of the meeting of the Medical Officer of Schools Association on the 24th ult. I did not state (as reported) that in my opinion the certificates obtained from parents as to the recent exposure of school children to known sources of infectious disease were utterly worthless. On the contrary, I expressed my belief in the great value and importance of requiring such certificates to be properly filled in and signed by the parent or guardian upon each occasion of the child's return to school; and I should still hold such certificates to be of value, even though their influence were limited to directing the parent's attention to sanitary precautions, the necessity for which may otherwise be too easily ignored or forgotten.

I am, Sir, yours faithfully,

Hertford, Aug. 6th, 1884. C. E. SHELLY.

[1] "Nursery Hints" (London: Chatto and Windus). [illegible]—ED.

MEDICAL STUDENTS IN GERMANY.

THE following figures show the number of medical students at the chief German universities during this term:—Berlin, 224, including 20 from America, 6 from Asia, and 2 from Africa; Jena, 162; Bonn, 239; Königsberg, 267; Halle, 282; Göttingen, 189; Giessen, 126; Tübingen, 224; Strassburg, 172. The autumn cyclus of the holiday course of lectures for practising medical men will take place at Berlin from Sept. 24th to the end of October.

A M.D. of Twenty Years' Standing.—There is one fatal objection to our correspondent's proposals: they are utterly impracticable. Let him reflect on the impossibility of passing a Medical Bill through Parliament with the most moderate proposals, and he will see the impracticability of such suggestions as he makes.

Dr. James Tidy.—The card should be forwarded to the bodies from which the person in question obtained his qualification, with a request that they will administer reproof. As regards the public, there is nothing to hope for but increased intelligence as to the meaning of thorough vaccination.

FATAL CASE OF ACUTE INVAGINATION OF ILEUM.

To the Editor of THE LANCET.

SIR,—The record of the following typical case may be worthy of a place in your esteemed journal.

Alice J——, aged eight years, was one of three children; the remaining two, aged respectively fourteen and sixteen years, were healthy. The mother was healthy, but the father had died at the age of thirty-six years of chronic phthisis. Alice was tall for her age, thin, and dark; her health was good and her bowels regular; her appetite for meat was indifferent, but for farinaceous food it was good. On July 15th she ate some cherries. On the next day her bowels were confined; otherwise she seemed well, and went as usual to school; she, however, refused her lunch, and, seeming ill, was sent home at twelve o'clock. A medical man saw her on the same day, and prescribed a purge. I saw the patient on the 16th; she then complained of abdominal pain, incessant vomiting, and constipation. Treatment was adopted, and she was ordered to bed. I again saw her in bed on July 21st. Her condition was worse than when first seen. She lay on her back, with the right leg flexed on the abdomen, complaining much of abdominal pain. Her arms were tossed about, and dark circles surrounded her eyes. The skin was cold and clammy, the face anxious and pinched-looking, and the tongue dry and brown; the pulse was small, fast, and feeble, and the respirations quick and shallow. There was incessant vomiting, the vomited matter being yellow and smelling offensive. The abdomen was distended, chiefly towards the middle line; large veins wandered over the integument of the chest and abdomen (a point noticed by the child's mother); the surface of the abdomen was irregularly undulated, due to distended coils of small intestine beneath. Deep down to the left of the cæcum, and almost at right angles to it, one could feel an elongated, firm, and tender mass obscurely through the intervening tissues. Neither gas, fæces, mucus, nor blood passed through the anus. Thirst was intense. On the evening of the 22nd the pain ceased, and on the following morning the vomiting ceased. In the evening the patient was drowsy, and there was a leaden hue of surface; the skin of exposed parts felt rough, and seemed obscurely papular about the face, and especially on the forehead. The patient died quietly on the night of the 24th.

The treatment consisted in perfect rest, eight-minim doses of tincture of opium, iced liquid diet given often in minute doses, voluminous injections of water, and afterwards of oil. During the last twenty-four hours before death opium was withheld. Operation was refused.

The condition of the body on examination twenty hours after death was as follows. Distended coils of small intestine rose into the incision; the large intestine throughout was collapsed and contracted. To the left of the cæcum lay a dark, hard, elongated tumour, consisting of the last six inches of the ileum, the left and upper three inches being invaginated into the right or cæcal portion; the peritoneal surfaces were glued together by recent lymph; the muscular coats were swollen and softened. The whole was of a purple colour. In undoing the invagination the softened bowel gave way to a small extent. The ileo-cæcal valve was not involved. There were no signs of general peritonitis.—I am, Sir, yours obediently,

JOHN MCMUNN, L.R.C.P., L.R.C.S.Ed.

Park-lane-terrace, Aug. 1st, 1884.

Mr. J. Wrixon.—Technically, perhaps not; but we know of no law which would make it easy to prosecute a gentleman with the qualification mentioned, and using the title now employed by any Licentiate of a College of Physicians who pleases to do so.

Medical Diary for the ensuing Week.

Monday, August 11.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

Tuesday, August 12.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, August 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, August 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday August, 15.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

Saturday, August 16.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year..... £1 12 6 | Six Months..... £0 16 3

TO CHINA AND INDIA..... One Year 1 16 10

TO THE COLONIES AND UNITED STATES .. Ditto 1 14 3

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

ABSTRACT OF AN ADDRESS ON THE INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE.[1]

By SIR WM. W. GULL, BART., M.D., F.R.S.

GENTLEMEN, FRIENDS, AND COLLEAGUES,—I esteem it a great honour to be deputed to address you on this occasion, and on a matter which promises to contribute to the advancement of medical knowledge by a wider and fuller method than has yet been sufficiently attempted. The subject of my address is the institution of an International Collective Investigation of Disease. This object, I need not say, is intimately connected with the main purpose of these Congresses, if not indeed in the natural course of things an integral part of them. At present we come together as individual cultivators, and practitioners of medical science, each contributing his quota to our knowledge on this or that subject which may or may not have been selected for thesis and discussion beforehand. Nor are our labours even under these conditions without excellent results. But a feeling is growing and already widespread, that by a more organised combination, a more intimate and better co-operation, not only the members of these Congresses, but all the working members of our profession throughout the civilised world, might sooner or later be organised into a body of fellow-workers, associated for collecting information on medical questions over the widest area. There is, perhaps, no profession which enforces upon its individual members so strongly as does Medicine the necessity of continued observation and intellectual cultivation, and there is no means by which this cultivation can be so well promoted as by meetings like the present, and by the active organisations in the form of committees or sub-committees which we hope and anticipate may spring from them. The human intellect in its single and separate operation may produce wonderful results. Yet isolated as a man may seem to be in the intellectual labour which occupies him, he makes but little progress apart from the aid and co-operation of other minds which have worked and are working in the same direction. And though doubtless it will always be the privilege of the highest intelligences to clear the boundaries of knowledge and to throw the rays of their genius into the surrounding darkness, yet all must be agreed on the great and almost supreme value of the intellectual co-operation of less gifted minds in the simple observation of facts, and especially when the needed facts are scattered over a wide field. However much apart, as I say, a man may seem in the work of his intellect, he is really much less so than he seems to be, for as we cannot refer the strength of our bodies to any particular food that we have taken, so neither can we track the thoughts of our minds to the sources whence they may have been fed; and if our social nature has been raised from savagery to civilisation by social combinations, it is even more necessary that our intellectual nature should be helped in its growth and nurture by such intercourse and association as are here presented, and which we now propose further to advance. Our great countryman, Bacon, has not generally been well received in the school of German philosophy, so that I must use some caution in citing him in favour of intellectual combinations in pursuit of the sciences. Still, on thinking over the bearings of collective investigation of disease, I could not but feel that although three centuries have elapsed since he broached this question, and little has been done in it since, we might be about to realise his idea of a Novum Organon, the formation of a new intellectual machine for removing and overcoming the obstacles of our medical progress. The purpose we have before us is no less than this, to enlarge and methodise intellectual co-operation, whereby not only the active but the at present inactive faculties of observation of the wide-spread members of our profession may be combined into one or more lines of energy. I am not unmindful how much this presupposes; how it assumes the combination of exact observation and record, with refined criticism and analysis; how it demands the highest scientific perception, with the humble collection of the meanest facts; how, in fine, it means the development of intellectual combination into many forms of organisation which should be not one but many instruments of research. Such a forecast may perhaps lead us to exclaim, "Who is sufficient for these things?" Yet happily the answer is near; time, though short for the individual, is inexhaustible in the race: the intellect is in its infancy, its powers of growth unexhausted; and to these in their evolution there appears to be no limit. The work to be done is unchangeable, and there are eager and willing workers in all lands, who only need the encouragement and direction of the master-minds of medical science to set them to work. Happily, the phenomena which demand our investigation, though complicated and transient, are, it need not be said, the result of unchangeable laws. The capriciousness of Nature, as we speak of it, is but the weakness of our own sense and understanding, and its so-called mystery and obscurity but the darkness in ourselves. The physiologist and the pathologist have to admit that not even in the caprices of man is there capriciousness; that mental caprices have their organic basis; that the whims, the fancies, and the prejudices of the human mind, not less than the changing activities of the functions of his body, or the revolution of the earth on which he lives, are but the resultants of unvarying laws, unchangeable as the fixity of the stars on which he gazes with wonder and admiration. We may therefore have this encouragement, that when any of our work is done, however small and trifling it may seem, it is done and settled for all time, or at least so long as the laws of organisation remain what they are; that the clearing of a fact in respect of disease will remain an imperishable inheritance of knowledge to those who follow us, so long as there is disease in the world. We may support our labours, therefore, with a feeling of surety that the problem before us is a settled problem, however difficult its solution. Nature will not delude us, however much we may delude ourselves.

A superficial survey of the sections of this Congress shows that the student of medicine occupies a unique position in the pursuit of knowledge. For instance, if I turn the leaves of the programme I find that the section of Anatomy invites attention to cell nucleus and cell division, the lowest unit of organisation; and the section of Psychiatry to the psychic-epileptic equivalent, which, as one will deny, stretches to the other pole of knowledge; hence, surely no man more needs to lay hold of the unchanging idea of law than the student of medicine, as he ranges from one extreme of observation to another. In the international investigation of disease, the prevalence of mental disorders in different nations will be a subject of inquiry. Also the forms which these maladies take, according to nationality, occupation, stratum of society in which they occur, &c.; the use of stimulants—alcohol, opium, hemp, tobacco, &c. This work obviously lies not only in the physical and physiological conditions of life, but in their intimate correlatives, the facts of psychology. The thoughts of the student of medicine must, therefore, range from the atoms that build up the textures to the hopes that make the man; and even, perhaps, further than this, for in most of us the unsatisfied mind cannot answer itself with the measurables and ponderables of physical science, however much it may admit that all else is dependent upon them, but will strive to go behind appearances and feelings to the substratum of their existence, and cannot find rest for its foot until it traces their relation to an unchangeable first cause. Du Bois Reymond might well remark that the problem of organisation would be comparatively easy if it were unattended with feeling and thought. That it would then, as it were, present us only with an astronomical problem in which the atoms of things would, after the manner of the heavenly bodies, move on in their several orbits in lines which science might hope to deal with. For it is within the scope of science, even as we now understand it, to track an atom of oxygen, nitrogen, hydrogen, or carbon through its synthesis in a plant to its combination in the elements of brain or muscle, and still on to its resolution and return into its original form, with corresponding evolution of force. But when this shall have been done, we have learnt nothing of pain, nothing of emotion, nothing, indeed, of the science of many of the common facts with which medicine has to deal every day.

[1] Delivered at the International Medical Congress, held at Copenhagen in August, 1884.

How different would be the problem for the physician if disease were unattended by pain or emotion, if the patient were indeed patient as unorganised materials are; if there were no hopes or fears on the part of the object to be dealt with, and no embarrassment on the part of the practitioner from desire to please as well as to heal! Quacks would then be banished to limbo. The course of nature could be watched until the equilibrium of health was attained, and the temptations to polypharmacy would be no more. But then, on the other hand, we should have nothing to do with life in its higher form, which is our ever-abiding problem, and we should miss the stimulus of affection, which, like a constant trade wind, carries us forward—at least the majority of us. If for these preliminary remarks I need any apology, might I not say that I have come from the country of Newton and Harvey, that I have travelled by the home of Spinoza, and that I am speaking in the presence of the countrymen of Descartes and Leibnitz.

Gentlemen, I do not appear here to-day on my own behalf, but on behalf of the Collective Investigation Committee of the British Medical Association. For some years past, and especially during the last four years, it has been felt that the aims of this great Association might be advanced to a higher point by establishing an organised plan of medical observation amongst its members, and, already, sub-committees to the number of fifty, comprising as many as a thousand members, have been established to carry forward this proposition. I am deputed by the Central Committee of this Association to ask you to-day to extend this combination by establishing an International Committee for the Collective Investigation of Disease, and I trust this may commend itself to the Congress. Such an International Committee would have objects entirely germane to the recognised purposes of the Congress itself. Probably one might go even further, and say that such an International Committee should form an integral part of these International Medical Congresses, and that their operation would in time become one of the most fertile sources of international medical advancement. I am happy to think that but little argument will be required in this assembly to commend this proposition to your favour. Already in Berlin the Verein für innere Medicin has adopted the principle, and has established a committee after the pattern of the British committee, to carry forward the work. The President of the Society, Professor Frerichs, has given his entire adhesion to the movement, and Professor Leyden has accepted the presidentship of the committee itself, which includes also very distinguished names; and I hope that one or more of our colleagues from Berlin will to-day add a few words in favour of the proposition I am called upon to make. In putting arguments forward for the establishment of a National Collective Investigation in its more limited form, it was permissible to insist upon minor advantages to be expected from such association—I refer to its educational value, since it could not but happen that every co-operating member would learn much from the investigations proposed; and that whilst he promoted science he would no less promote his own intellectual status. Amongst the subjects suggesting themselves to us in England in near relation to this matter was the formation of life-histories and family-histories in respect of disease, and these could only be obtained through the family physician. If such histories could be widely and accurately recorded, the natural associations of different forms of disease in individuals and families would be made evident, and might afford suggestions as to pathological relations not now suspected, relations between diseases which are separated in Nosological Treatises but associated in Nature. This mode of inquiry, through family history, would open a wide page for the record of the *pathology of ailments;* a page than which there is none more interesting to the practitioner of medicine, since seven-tenths of his work and perhaps more than this lie in efforts to correct physiological deficiences and to maintain some near approach to the equilibrium of health, which a feeble organism unaided cannot reach. On this part of the field it is that we can study the relations between functional and organic diseases, especially in the range of nervous affections, where the degenerative tissue changes in one individual of a family may be compared with the physiological disturbances in another. It is also in these family histories that we might hope to have elucidated the difficulties of *correlated pathologies.* Why, for instance, in a numerous family, whose members are living under the same conditions, one or two should become the subjects of pulmonary phthisis, one or two the victims of rheumatism, another of epilepsy, whilst the others maintain a healthy equilibrium. If such a history should be repeated in ten thousand families or in a hundred thousand, we surely might hope, by careful collation of the facts, to come to the groundwork of these differences, and to determine the rule which separates the epileptic and the rheumatic from the inroads of phthisis. So much for the more limited though not less important advantages of National Collective Investigation, but in an International Collective Investigation the ground widens very much, not only from the different intellectual characters of its working members, but also from the greater variety under which disease presents itself.

The first gain, no doubt, will be from the intercourse and reaction of different national modes of thought, with and upon each other. It need not be said that the ways in which any subject may be viewed do not depend upon the subject itself, but upon the varied capacity of the minds brought into relation to it. Minds evolved during ages under special local and national conditions, and education in lines of their own, cannot fail to give new direction and shape to the questions proposed for solution. All will admit that in the daily routine of practice facts are occurring that are worthy of record, and that medical science loses much by the want of such record. By the combinations proposed, what are now casual and wasted observations would be methodised and stored for arrangement, comparison, and deduction. The English Committee has proceeded as follows:—Having first determined certain subjects for collective investigation, cards of queries have been framed and distributed through the different sections, leaving each member to select such subject or subjects as he might prefer.

The clinical subjects which at present have been selected are acute pneumonia, chorea, acute rhematism, diphtheria, and inherited syphilis. Cards of queries have been issued on each of these subjects, and each card is accompanied by a memorandum stating the object of the particular inquiry, and directing the attention of the observer to the queries proposed. These memoranda are of the first importance in this movement. It is on them that our hopes of success must be grounded. It is intended that they should indicate the defective state of our knowledge in the subjects brought forward for investigation. In doing this their value to the profession, and to the progress of our knowledge, is almost incalculable. It is no small matter to have set before us in a simple manner what the present state of our knowledge is, the defects which have to be made good, and the inquiries likely to lead to such a result. Text-books on medicine will herafter have to follow something of this leading. Hitherto, and for the most part, they have aimed too much at satisfying the reader, and, in order to make the treatises complete, have assumed a knowledge both in pathology and therapeutics too little justified by fact, and so have hindered, rather than promoted, our progress. These memoranda are intended to be critical suggestions and suggestive criticisms on the state of knowledge respecting the subjects brought forward; they are the centre of the proposed system. It may fairly be expected that each issue of them will be more exact and incisive. The successful framing of them is the one important object to be attained. Through them the influence of the more advanced intellects in the profession will extend through the whole of it, and will reach its most scattered and distant members. Nor can we doubt but that there will be a reaction from the periphery to the centre, maintaining a living cycle of active mental co-operation. Who can limit the effect of such action and reaction, or deny that there will thus arise new energy and new genius? for, happily, the cultivation of science need not remain the privilege of professors and teachers, but may become the common inheritance of all.

The volumes I hold in my hand are the first published records of the collective investigations in England. They contain reports and memoranda on the communicability of phthisis, acute pneumonia, chorea, acute rhematism, and diphtheria. I would refer, by way of illustration of my remarks on memoranda, to the memorandum on acute rheumatism. This recites our deficiencies on the etiology of this disease, and might also include its pathology; the exceptional ways in which rheumatism occasionally developes; its probable relation to the state of the nervous system; the new aspect of the pathology of joint-affections in relation to the spinal cord; the relation of the intensity of the rheumatic affection to anæmia; its clinical relation to tonsillitis; the intercurrent affections of the skin; and, last, but, un-

Digitized by Google

happily, not least, the treatment. I might add, however, not as a criticism but as a suggestion, than an exhaustive memorandum on acute rheumatism, showing the real state of our knowledge respecting this disease in all its relations, and the more than vagueness of our treatment of it, would have a value which I should find it difficult to express. Long-standing prejudices, which for the most part are entertained and fostered as if they were established and confirmed experience, would go down before the exposition of such a memorandum and its results in international collective investigation, as dry leaves before an autumn wind.

Whilst our English Association has, as I have described, put forward several subjects for collective inquiry with the memoranda and questions I have named, our German colleagues have determined upon a somewhat different method. They have selected but one subject for investigation, thinking it better to exhaust that before taking up a second or third; and they have naturally selected a subject which at the moment prominently occupies the attention of the profession in all lands—I mean pulmonary phthisis. Upon this they have proposed four points for solution: (1) The heredity of the disease; (2) the communicability of the disease; (3) the cure of the disease; (4) the transition of pneumonia into phthisis. These propositions are accompanied with many questions of detail which I will mention presently. The English Committee, at the beginning of last year, also proposed as a question for Collective Investigation the communicability of phthisis, and have reported upon it. The German inquiry is not yet reported upon. The important discovery of Koch that there is a specific organism associated with pulmonary tubercle, and his infection experiments, have naturally excited the greatest interest respecting the communicability of the disease. It is well known that at different times and in different ways the contagiousness of phthisis has been confidently believed in; and, as Professor Ewald remarked at a meeting of the Verein für innere Medicin, observers in America, in England, and in Germany, have supported the belief in the contagiousness of phthisis by important records respecting it. Still, until Koch's discovery, the professional mind was very much asleep about it, or with only now and then a half-waking dream. The English Collective Investigation Committee have put forward the question of communicability in the simplest form, "Yes" or "No;" as follows: "Have you observed any case or cases in which pulmonary phthisis appeared to be communicated from one to another? Please answer Yes or No." It will be observed that this is not a mere voting question as to a man's belief, but whether he has observed any case or cases of the apparent communicability of the disease. "Out of the 1078 members of the Association who returned answers to the questions issued on this subject, at least 261 believed they had seen cases of phthisis which have originated in communication from one person to another; about 39 more have seen cases which have made them doubtful whether phthisis may not be so communicated; while 105 have offered facts and arguments which seem to them to negative such a view. One hundred and fifty-eight of the affirmative returns refer exclusively to cases observed between husband and wife. Communication between husband and wife is mentioned, together with other cases in 34 of the remaining returns. So that 192 observers report cases of supposed communication of phthisis occurring between husband and wife." There are also a number of special returns where the disease seems to have spread from patient to nurse, and from friend to friend. I am not here of course to discuss the pathology of phthisis or of its communicability from person to person, but to argue for the advantages of collective research. And, perhaps, no subject could be selected better to demonstrate these advantages than the supposed contagiousness of phthisis. By extending the inquiry over a wide area, the recurrence of striking cases of apparent communicability are repeated over and over again, and, must naturally impress the mind more than a case or two occurring in individual experience. The Committee, therefore, justly remark in their report, that they hope that this first step in collective investigation into one of the most important questions connected with the etiology of phthisis will be of value in leading to more open-mindedness in the discussion of disputed questions of experience and observation. We shall await with interest the report of the Berlin Committee, for its Cards and Queries is much beyond that of "Yes" or "No." It presents seven sections:—(1) General questions as to the history of the family of the patient the subject of phthisis; (2) Antecedents of the family; (3) Previous diseases of the patient, as, for instance, whether of phthisical habit or not, what diseases preceded the development of phthisis, as scrofula, measles, whooping-cough, chlorosis, &c.; (4) On the question of heredity follow queries on health of parents: Either dead of phthisis, and when? Have they suffered from scrofula, disease of the bones, lung diseases not phthisical, as pneumonia, pleurisy, gangrene, bronchitis, &c.? Were the grandparents or parents related in blood? Age of father or mother at the birth of the patient? Were they sober or not? &c.; (5) On contagiousness or communicability—was the disease taken from husband by wife? or from wife by husband? when the malady began? was the communicability between brothers and sisters, or relatives or servants? was the contagion from residence in prisons, establishments for the insane, barracks or infirmaries, &c.? was the infection by residence, clothing, or beds? by nourishment, as through the milk of scrofulous animals or consumptive nurses, &c.? (6) On the curability, including only such cases where at least two years had elapsed from the beginning of the disease—where did the arrest or cure seem to begin? did this come from the improvement of the general condition? are cough and expectoration gone? have the physical conditions altered, and in what way, &c.? (7) On the transition of pneumonia into phthisis—the day of the beginning of the pneumonia? its seat, as at base, apex, or middle of lung, &c.? right or left lung? expectoration—sanguineous? rusty? grass-green, &c.? signs of re-convalescence? when the first signs of tubercle occurred? &c. &c.

In the time at my disposal it is impossible to sketch, even in outline, the number of subjects which claim attention. The committees of the different sections, as the work progresses, will select their subjects from their own point of view; some with a broader purpose will take the more common maladies, and the more curious the rarer ones. One of our English colleagues would have concise descriptions of rare maladies, prepared as an entomologist would have them prepared, of newly-discovered insects, printing distinguishing features in italics. He instances rhinescleroma; Hebra's prurigo; morphœa; Alibert's keloid of scars; Addison's disease; Hodgkin's disease; cretinoid state in the adult (myxœdema); congenital absence of special bones (such as radius and tibia, with associated portions of carpus or tarsus); cases of spina bifida, illustrating either results of treatment or survival without it; cases of sacral tumour; cases of the recurring iritis in young persons; aneurysms in the orbit; the osteitis deformans of Paget; disease of joints in ataxy; (Charcot's joint disease); non-malignant growths in the tongue; hemiglossitis; and Kaposi's disease.

The arguments for these more curious inquiries are not far to seek, since diseases which are rare in some countries may be frequent in others, and by their frequency afford the required ground for the study of their pathology. I might instance the glandular and elephantoid diseases of China, and the successful labours of Manson and Mayers, which have traced them to the presence of the *filaria sanguinis hominis*, producing lymphatic obstructions and filarial thromboses. The elucidation of such a piece of pathology, though the disease be limited to China, must have a good influence on the whole medical mind in breaking down preconceived opinions, and in showing that we cannot go too far afield for our knowledge. It supplies, moreover, a further argument for the International Collective Investigation of Disease.

Gentlemen, whilst I thank you for the favour with which you have received this address, I cannot but express my deep sense of the imperfect way in which I have set forth the greatness and importance of my subject. I can now but commend the matter to your good efforts, assured that, through them, success will not be wanting.

PETITION FOR INCORPORATION.—A petition has been presented to Her Majesty in Council by the Earl of Jersey and others, and the Chancellor, masters, and scholars of the University of Oxford, praying for the grant of a charter for the incorporation of the president and governors of the Radcliffe Infirmary, Oxford. They have been referred to a Committee of the Privy Council, by whom they will be considered on September 25th. A petition has also been addressed to Her Majesty in Council by Dr. Henry J. Littlejohn and others, praying that a charter of incorporation may be granted to the Queen's College, Edinburgh.

ABSTRACT OF A Lecture ON THE REARING OF HAND-FED INFANTS.

BY EDMUND OWEN, F.R.C.S.,
SURGEON TO ST. MARY'S HOSPITAL, AND TO THE CHILDREN'S HOSPITAL, GREAT ORMOND STREET.

ON August 1st Mr. Edmund Owen delivered a lecture on this subject at the International Health Exhibition. The chair was occupied by Dr. Charles West, who, in introducing the lecturer, made an eloquent address upon the sacred duty of mothers suckling their own infants. He severely criticised the system of wet-nursing, by which one infant was robbed of its birthright for the sake of another, whose wealthy and indifferent mother might be shirking her responsibility from mere indolence.

Mr. Owen remarked that probably almost everyone would agree with the truth of the general proposition, that for the first half-year of infant life the mother's milk should be the only food for babes; but where a poor woman has to leave her infant in order to earn money for the support of her husband, or where the lady of fashion finds that the claims of society are so strong as to efface the sweet duties of motherhood, the question had to be answered as to the best artificial food. The physiological chemist brought in his answer: having made an analysis of human milk, he prepared a patent food which, he thought, ought to be even superior to the original article; but his compound was never absolutely fresh, and, when reared on it infants were too apt to grow weak and flabby; most likely it contained some starchy element which found no representative in human milk; he might almost as well put in fine sawdust.

The lecturer said that he was apprehensive lest preserved milk should entirely usurp the place of fresh milk in the nursery. At present it was far too widely employed; and he entirely failed to see how it could form a more wholesome diet for infants—as some maintained it did—than the fresh article. He could no more believe this than that the adult would thrive better on tinned American meat than on fresh sirloin. For babies, cow's milk, which should be always fresh, should be mixed with an equal or *even greater bulk* of warm water, in which a lump of white sugar and a pinch of salt had been dissolved; the fresh milk was an excellent antiscorbutic, and was therefore always needed. Often, when he had been assured that cow's milk could not be retained by the infant stomach, he had been able to demonstrate to the contrary by mixing even as much as double the quantity of water with it. In summer lime-water might be added to the mixture.

As regarded feeding-bottles, Mr. Owen said that the old-fashioned long straight one, with the short indiarubber nipple, and with no tube at all, was the best; and he wished that, in their search for the antique, mothers would revert to the use of the ancient feeder. With this the infant could be fed only when the nurse had the bottle in her hand, so that the child's meals would be given at regular intervals and for a definite time, and under close watching. The very worst kind of feeder was that now in general use; he had heard it called by one well competent to form an opinion on the matter "the lazy nurse's bottle." It was not so easily kept clean as the slipper-bottle, and was liable to many and serious abuses. Infants should be fed at regular intervals, and if they vomit after their milk, they should be fed on smaller quantities, given at shorter intervals. As a rule, for the first month the bottle should be given every two hours, gradually increasing the interval to three and eventually to four hours. As time went on, less and less water should be added to the milk. Too often infants were fed simply because they cried. True, the infant has "no language but a cry," but the cry may mean that the stomach is already overloaded. Before the end of the first year infants should be entirely weaned from the bottle; they should then have daily a little undercooked meat pounded into a pulp, to which some gravy and salt have been added. Potato finely mashed and covered with gravy, an egg, or a little milk pudding, may vary the diet. But on no account should they be allowed any wine, beer, tea, or coffee, though they may have cocoa and milk. The meals should be given regularly; children should not be allowed to "pick" at bread-and-butter, cakes, and sweetmeats in the intervals.

Having criticised unfavourably the absurd fashion of bunching all the little child's clothes around the middle of its body, the lecturer pleaded that here, at any rate, there was great need for a "scheme of redistribution." The body should be evenly covered. Children could not be hardened by cold baths or by any other exposure to cold; only the very fit could survive such severe treatment. Like flowers and fruit, they loved warmth and sunlight; and when he had a sick child under observation he made it one of his first cares to have the cot placed in a sunny part of the room. In England people did not seem to know the value of sunlight; the Italians did, however, and their common saying was to the effect that "where the sun does not go the doctor does." The sun's rays have a destructive influence on suspicious or baneful gases; but to such vapours children should never be exposed. No bath, sink, or closet should be allowed near the nursery; many children fell victims to a neglect of this first law of domestic sanitation. Everything about them should be sweet and fresh, and there should be no carpets nor bed or window-hangings to interfere with the free circulation of the air. On no account should the infant be taken to sleep in its mother's bed; the coroner for Central Middlesex holds a hundred and twenty inquests every year on infants who have thus perished. If the weather be very cold, a warm brick or bottle wrapped in flannel might be tucked in under the clothes of the cot. For ensuring appetite, digestion, and sleep, the infant should be taken out of doors each day when the weather is fine; and every day, unless a bitter wind is blowing, or it is foggy, the window should be thrown open for a while, as fresh air in the house is an absolute necessity. A well-managed babe should close its eyes as certainly as does a mechanical wax-doll as soon as it is laid down for sleep. The small hours of the night and the unhappy husband need never be disturbed by cradle-songs and lullabys. It was only a home-sick sugar-planter who cried "Rock me to sleep, mother!" and probably if an infant could speak it would never be heard repeating the request.

In conclusion, the lecturer likened his discourse to a badly-made net, in which the irregularly-sized meshes were represented by the many faults of omission and commission. Still, he did not fear the net breaking under the test of practical experience. Indeed, the greater the strain it was thus called upon to bear, the more productive would he consider this his cast. And he was of opinion that if the great Health Exhibition did nothing more than direct public attention to the unsatisfactory environment of hand-fed infants, history would still be fully justified in regarding it as one of the most important national successes of the nineteenth century.

THE PATHOLOGY AND TREATMENT OF CHOLERA.

BY ALEXANDER HARKIN, M.D., F.R.C.S.,
CONSULTING PHYSICIAN TO THE MATER INFIRMORUM HOSPITAL, BELFAST.

THE subject of cholera in all its relations has, from its near approach to our shores, become of pressing importance. Great attention has been properly given to its etiology and prophylaxis; but as, notwithstanding all our efforts, we may not succeed in keeping the enemy at bay or combating him at long range, as he may possibly break into our camp and challenge us to a hand-to-hand encounter, it is all important that we decide with what weapons we shall be armed for the fray. As matters stand, there is no reliable programme, no authoritative pronouncement by our medical corporations, as to the best method of procedure; and thus it falls to the lot of individuals to formulate their views and to advocate their adoption, on the grounds of practical experience or scientific teaching. But that I have had lengthened experience in the treatment of cholera, dating from its second advent in this country up till its latest appearance, having been pupil and assistant to my venerated friend Dr. Henry MacCormac, in the Belfast Cholera Hospital, and because I have some important observations of an original nature to submit, I should not possibly have undertaken the present task.

Digitized by Google

Whatever the primary or the remote cause of an attack of cholera, whether miasm or bacillus, the influence of the nervous system becomes rapidly manifested. The prominent symptoms of purging and vomiting appear to be due to an abnormal condition of the nerves supplying the stomach and bowels; the choleraic voice, the vertigo, tremors, and muscular cramps betray their nervous origin; the symptoms of collapse are evidently caused by great irritation of the sympathetic system; while to the influence of the vaso-motor system may be attributed the depression of the functions of respiration and circulation—the chief dangers of the disease. We may recognise additional evidence of nervous agency in the sudden deaths which occur in every epidemic, when men are stricken down fatally after one or two hours' illness, as if poisoned by prussic acid or the concentrated virus of the upas tree, and in those rapid recoveries that we often witness, forbidding the idea of any serious complication or organic affection having caused or accompanied the most lethal symptoms. Under such circumstances, it is evident that our exertions should be directed towards combating the nervous factors in the disease.

The disease and its treatment naturally divide themselves into three stages: the preliminary, or diarrhœal; the stage of violent purging and vomiting, and cramps; and that of collapse.

For the diarrhœa nothing in my experience answers so well as dilute sulphuric acid, which should be administered every hour in doses of twenty to thirty drops in some agreeable menstruum, with mustard or turpentine epithems to the abdominal region, and iced water when available *ad libitum*. Should the second stage supervene, it is necessary to take decisive steps lest the third rapidly develop.

It is in the second stage that my peculiar experience becomes available. Physiologists teach that the phenomena of vomiting and purging depend altogether upon the nervous mechanism of the organs affected. According to Michael Foster, "the dilatation of the cardiac orifice is caused, in part at least, by efferent impulses descending the vagi, since, when these are cut, real vomiting with discharge of the gastric contents is difficult, through want of readiness in the dilatation. Since the vagus acts as an efferent nerve in causing the dilatation of the cardiac orifice so essential to the act of vomiting, it is difficult to eliminate the share taken by the vagus as an afferent nerve carrying up impulses from the stomach to the vomiting centre" (pages 275-6). The influence of the vagus is thus demonstrated in the act of vomiting, both as an afferent and an efferent conductor of nervous energy. Kolman, too, quoted by Hall,[1] has shown that the right pneumogastric supplies the whole of the small intestines. "This is an inhibitory nerve," he says; "and Moreau and Lauder Brunton have demonstrated that the division of all the nerves going to a portion of intestine is followed by the secretion of a fluid just like rice-water stools of cholera. May not the stimulation," Hall continues, "of the inhibitory vagus be followed by results much the same as if the sympathetic supplying the small intestine were paralysed?" In accordance with these physiological views, I have latterly treated every case of English cholera in the second stage by remedies applied to the pneumogastric nerve in the cervical region, with the satisfactory result of putting an end at once to the profuse vomiting and purging so characteristic of this stage. Arguing from its controlling effect in extreme cases of English cholera and cholera infantum, which our best authors say differ only in degree from the Asiatic type, I have every confidence that it will prove equally useful should the latter epidemic gain a footing in this country. There is another important indication, which will be subserved by counter-irritation over the vagus—viz., the restoration of the cardio-inhibitory function of that nerve; thus the violent contraction of the heart will be controlled, the expansive power of its cavities restored, and the congestion of the pulmonary and arterial system put an end to. The application I have always used is the epispastic solution of the Pharmacopœia applied freely with a brush behind the ear and in the neck as far as the angle of the lower jaw. No matter how violent the vomiting or purging, I have never failed in stopping both by this application; a stimulating effect is produced at once, and with it all gastric disturbances cease.

For the stage of collapse, which, according to Claude Bernard, is due to great irritation and hypertrophy of the sympathetic nervous system, Dr. Hall, who has seen a large amount of cholera in India,[2] proposed to the Royal Medical and Chirurgical Society of London, on October 13th, 1874, a plan of treatment which received the approval of the Society, as well as of Sir Joseph Fayrer, who was present. He recommends the subcutaneous injection of a solution of chloral hydrate, 10 grains in 100 parts of water, in four or five different places, according to the size of the syringe. If reaction does not commence in an hour, he injects again. The sedative soothes the contracted nerves, and relaxes the contracted vessels; the blood is once more uniformly distributed, and consequently the pulse reappears at the wrist, the cramps and abdominal pains subside, sleep is induced, the respiration becomes regular, the discharges lessen, the face fills out, the voice becomes stronger, and the natural secretions are restored. Mr. Higginson, in his report to the Deputy Commissioner at Keri, Oude, states that he has treated nineteen cases of cholera according to Dr. Hall's method, of whom seventeen recovered, being about 89 per cent of cures. For purposes of illustration I append a statement of two cases out of many which I treated during last autumn.

CASE 1. *English Cholera.*—Constable C—— sent for me on Sept. 18th, 1883, at 8.30 A.M. I found him in the act of vomiting, with small quick pulse, violent cramps, fœcid, palpitation of the heart, great debility, faintness, and coldness of the extremities. He was purged at frequent intervals, and the dejections were of the rice-water characteristic. He informed me that when on duty in the police-cells at 4 A.M. that day, he was attacked with profuse vomiting, followed in an hour by violent purging, with cramps, an attack occurring about every fifteen minutes. I did not order him any medicine, but painted him at once in the hollow behind the ears down to the angle of the jaw with an epispastic solution, assuring him that he would not have any return of his symptoms. I visited him again at 10.30 A.M., and found him quite convalescent, not having had any sickness or suffering, as I predicted.

CASE 2. *Cholera Infantum.*—On Sept. 24th, 1883, I was summoned to see a child living in Upton-street, Belfast, aged twenty months, at 11.30 P.M. I found it lying on its face across its mother's knee, with its arms and legs lying listlessly at either side; it was purging and vomiting at the same time. The child was almost pulseless, and was cold and feeble. The mother informed me that it had sickness at 6 P.M., and that it had vomited at least every quarter of an hour till the time of my arrival. She attributed its illness to a mess of soup which it had taken the previous day. She had administered milk with lime-water without any benefit. I did not recommend any medicine, but, having had the child placed on its back, I painted it with the blistering fluid behind both ears, informing the mother that from that moment both vomiting and purging would cease. Soon after the application of the remedy the child began to improve, the heat returned to the extremities, and at the end of half an hour it was fast asleep, when I left for the night. Calling at 10 A.M. the next day, I saw the child in its mother's arms looking quite lively and well. As I foretold, both vomiting and purging had instantaneously ceased.

There is no need of multiplying examples; these two are the representatives of a great number, irrespective of cases of bilious vomiting and gastritis from alcoholism, similarly and successfully treated.

In the cases related I applied the remedy behind both ears; in several others I found the single application behind the right ear sufficient for the purpose; and this appears to me preferable to the double blister, as, from its powerful inhibitory effect upon the heart as well as upon the abdominal viscera, the modified application is perhaps the safer. In these cases of severe suffering anyone can understand the satisfaction that is felt when he is justified in saying, "Permit me to apply this external remedy, and all your troubles will at once depart."

THE MENTAL ELEMENT IN THE ETIOLOGY OF GOUT.

BY J. MORTIMER GRANVILLE, M.D., M.R.C.P.

RATHER more than three years ago[1] I drew attention to this interesting and important subject. At that date the *rôle* of the cerebrum in the development of gout was scarcely recognised, and the part which the nervous system, as a whole, plays in the malady, although beginning to attract attention, had scarcely asserted its claim to consideration. A communication from Dr. Dyce Duckworth, made to me subsequently to the appearance of my letter in THE LANCET, brought to my knowledge the fact that he had discussed what I may, perhaps, call the cerebro-spinal hypothesis with his well-known care and ability. Other English writers, of course, had treated the subject from the neurological standpoint, but Dr. Dyce Duckworth's concise paper cast the facts and deductions in a practical form with great perspicuity. During the last three years progress has been made in the physiology—I will not use that unsatisfactory and misleading term *pathology*—of the disease, and I think I may now fairly claim that the view I dared to propound—namely, that a uric acid centre, either eliminative or destructive (Bernard or Pavy, in principle, *mutatis mutandis*) exists, and is, probably, located beneath the floor of the fourth ventricle, not far from, and in functional relation with, the so-called "diabetic" and polyuric centres. On the Continent and in America, if not yet in England, my view is accepted. My present purpose is limited to the recognition of two clinical facts and the making of one therapeutic suggestion.

An "attack" of gout is particularly likely to occur, in the gouty subject, at either of two mental or cerebral crises. First, on the eve of a great mental effort, when the brain is, as it were, charged to the highest point of tension with what, for want of a better term, we call nervous energy. The type of a paroxysm so occurring is likely to be "nervous," with severe neuralgic pains, if the patient be neurotic, or visceral in the sense of attacking one of the large organs if he be robust and of an active habit. Second, an attack of gout is likely to occur at the end of an intellectual effort, when the centres are exhausted; and in this case it may take the form of an epileptiform fit or syncope, followed by a more or less prolonged depression; or it may rapidly develop into a formulated arthritis of the ordinary type. In the break down before action I think the cerebral strength itself gives way; while in the paroxysm after exertion the attack occurs because the inhibitory control of the cerebral centres over the medullary, spinal, and organic centres is suddenly suspended. The attack of gout has, so to say, been kept in abeyance during the period of cerebral activity, and breaks out immediately this ends. The former class of cases is the most serious, and attacks of this class go far to prove the existence of a neurosis, for which the patient will require to be specially treated. The second class of cases is one in which the malady proper, rather than the patient, if I may so express myself, demands the practitioner's greatest attention.

The therapeutic suggestion I have to make is that the treatment of gout in all its forms should be based on the recognition that the uric acid can only be got rid of by a process of oxygenation, and that it must pass off by the kidneys, never by the bowels. Purgatives in gout are always harmful in direct proportion as they promote the discharge of fluid from the intestinal surface and leave the renal secretion concentrated, so that the uric acid, which requires a very large proportion of fluid for its solution, blocks the tubes of the kidneys in the form of crystals. One reason for the specially frequent occurrence of these attacks in warm weather is the loss of fluid by perspiration, and consequent concentration of the kidney excretion. If uric acid can crystallise, it *will*. I would only add that I am obtaining marked and satisfactory results in acute and subacute gout from the use of the following mixture. It relieves the pain almost immediately, reduces swellings, and raises the proportion of urea in the urine—as readily estimated by the hypo-bromite test—from 50 to 100 per cent. in a few hours. I *never* use colchicum, and I do not get either organic complications or serious depression. I do not starve my patients, or cut off their supplies of nitrogenous food; because I believe a vigorously trophic state is physiologically necessary to facilitate the oxidation of the uric acid, and to secure the due and rapid elimination of the products of disassimilation, as urea. I have now employed this formula in a very large number of cases, and with so much success, that I cannot hesitate to urge its consideration on my fellow practitioners:—Ammonii chloridi, ʒiv.; potassæ chloratis, ʒij.; glycerini, ʒxii.; tincturæ iodi, ʒij.; aquæ ad ʒxii. Misce. Fiat mistura, cujus sumantur cochlearia duo magna tertia, quarta, vel sexta quaque hora.

Welbeck-street, W.

[1] THE LANCET, April 23rd, 1881.

CASE OF

TETANUS TREATED BY HYDRATE OF CHLORAL; RECOVERY.

BY JAMES TAYLOR, F.R.C.S.,
SENIOR SURGEON TO THE CHESTER GENERAL INFIRMARY.

THE following case is recorded for the purpose of showing the power that chloral has over the convulsions of tetanus, and also the extent to which the drug may be given in such cases. Several times during the illness we considered anxiously whether we were justified in administering chloral so freely, but when we stopped it the tetanic symptoms became in a very short time so severe that we were compelled to resort to it again.

Mr. J——, aged forty-two, came under the care of Dr. John Roberts and myself, suffering from a malignant growth at the anus, which I removed on January 31st, 1884. He progressed favourably until February 9th, when he complained of tenderness about the jaws, which he attributed to eating a tough mutton chop. On the 11th he complained of being unable to open his mouth, and his masseters were rigid. Opium was given. On the 13th he was much worse. Any attempt to swallow brought on an attack of choking. The opium was stopped, and fifteen grains of hydrate of chloral given every three hours; in the evening this was increased to twenty grains every three hours. On the 16th, the spasmodic condition being much relieved, the chloral was stopped. On the morning of the 17th bromide of ammonium was prescribed. At 7.30 P.M. he was suddenly seized with violent general convulsions, which occurred every five minutes; his abdominal muscles were completely rigid; during the convulsions he screamed in agony; there was opisthotonos. twenty grains of chloral were given, and repeated at 8.30 P.M. At 9 P.M. the convulsions ceased, leaving him rigid. The chloral was continued every three hours until the evening of the 18th, when, the rigidity having passed off, it was again stopped.—19th: Cramp in the left side; ten grains of chloral were given. At 11.30 A.M. cramp in the thighs occurred, the hamstrings being very tense; he had twenty grains of chloral. At 8.30 P.M. there was violent trepidation of the legs when he rested on his heels; ten grains of chloral were given every three hours. On the 20th the least movement brought on violent trepidation. On the 21st he was very restless; constant trepidation existed, which was worse in the left calf; heart's action very irregular.—22nd: Very restless; irregularity of heart's action great. Stopped chloral, and gave him opium and carbonate of ammonia.—8.30 P.M.: Heart's action better, but intermittent.—23rd (10 A.M.): Violent general convulsions every few minutes, with great rigidity. Twenty grains of chloral and inhalation of chloroform. The convulsions had somewhat diminished at 12 noon. At 12.45 the chloral (twenty grains) was repeated, and was given every two hours.—24th: Restless and delirious; no violent convulsions. Chloral every four hours.—26th: Has had only slight spasmodic attacks the last two days. Was not to have the chloral unless more severe attacks occurred.—27th: Trepidation very severe, and pain in feet. Chloral thirty grains.—28th: Pulse very irregular. To have as little chloral as possible.—29th: Very restless; tongue very dry.

Until March 4th the patient was obliged to have twenty grains of chloral three or four times daily. Owing to the extreme irregularity of the heart's action and the constant delirium, the chloral was stopped on the morning of the 4th. At 7.30 P.M. he was suddenly attacked with violent general convulsions, and twenty grains of chloral were given; at 9 P.M. the convulsions occurred every few minutes, and

Digitized by Google

twenty-five grains of chloral were administered. The convulsions ceased in half-an-hour, the extreme rigidity leaving first the left leg, then the right, and then the back. On the 5th twenty grains of chloral were given every six hours. On the 6th and 7th the cramp was troublesome but there were no violent convulsions. On the 8th chloral was given every seven hours, and on the 9th every eight hours. On the 10th the dose was reduced to fifteen grains every ten hours. On the 11th there was return of severe cramp in the abdominal muscles, but twenty grains of chloral relieved it in a few minutes. On the 13th fifteen grains of chloral were given every nine hours, and on the 14th every twelve hours. On the 17th the patient only had chloral once in twenty-four hours. On the 18th there was still pain in in the leg, but he felt much better. The appetite was voracious, but he could not masticate on account of stiffness of the jaw. On the 20th no chloral was administered. Recovery was uninterrupted after this. On the 31st the only remnant of the tetanus was a feeling of weakness in the left leg. From February 13th to March 19th he had taken six ounces and three drachms and a half of chloral.

ACUTE MANIA TREATED WITH HYOSCYAMIN.

By C. THEODORE EWART, M.B., M.Ch. Aber.

I HAVE tried this alkaloid in twelve cases of acute mania, and have found it answer admirably. Although there is nothing novel in what I have to state regarding its action, I thought it might be of some interest to give the following six cases.

CASE 1.—C. A——, male, aged sixty-one; not epileptic. About every fourth month he suffers from delusional mania, which lasts for two months. During this period he is very noisy, shouting loudly or muttering incoherently. He sleeps but little. After these brain storms he becomes quiet and tractable. Thinking that hyoscyamin might shorten the attack, I ordered one grain. Although the sleep produced was very profound, the breathing stertorous, and the paralysis most marked, the pulse throughout was good, beating steadily and regularly. I decided, however, in future to give a smaller dose. The attack was not shortened by any appreciable length of time.

CASE 2.—F. W——, male, aged thirty-six, well-built and muscular. Formerly in the Artillery; served in India for a few years. Has had sunstroke. Is epileptic. Tongue furred and bowels constipated. Is so violent and excited that he has had to be placed in seclusion; struck one of the attendants severely. Ordered three-quarters of a grain of hyoscyamin at bedtime. Was sleeping quietly in ten minutes. Awoke in the morning much quieter, although still suffering from delusions. Gave an aperient draught. Kept in seclusion three days, and then allowed out into the grounds.

CASE 3.—J. C——, male, aged forty-four. Not epileptic. Supposed cause, a fall. Tongue coated, breath offensive, and bowels constipated. Is very noisy and excited. Had to be placed in seclusion. Beat the door continually, fancying he was crushing blackberries. Imagined he had met God and the devil; the latter he knocked down. Ordered three-quarters of a grain of hyoscyamin. Was asleep in a short time. Passed a quiet night; more rational in conversation. Gave an aperient draught. In four days he was allowed out.

CASE 4.—G. B——, male, aged thirty-eight. Supposed cause, religion. Not epileptic. Most noisy and unmanageable; converses in a loud tone with imaginary persons; face flushed; excited expression of eyes; required four attendants to restrain him. Ordered three-quarters of a grain of hyoscyamin. Within a quarter of an hour he was sleeping profoundly, and did not awake till 6 A.M., having had twelve hours' refreshing sleep. More quiet. Had to be fed twice. Repeated the draught at bedtime. On the third day he was sent to the infirmary ward, as he was suffering from an inflamed knee. Very deluded, but is free from excitement.

CASE 5.—W. E——, male, aged forty-four. Is epileptic. Suffering from an outburst of maniacal excitement, endangering the safety of the other inmates. Placed in seclusion. Given half a grain of hyoscyamin, which produced deep and prolonged sleep. Much quieter on waking. Allowed out the following day.

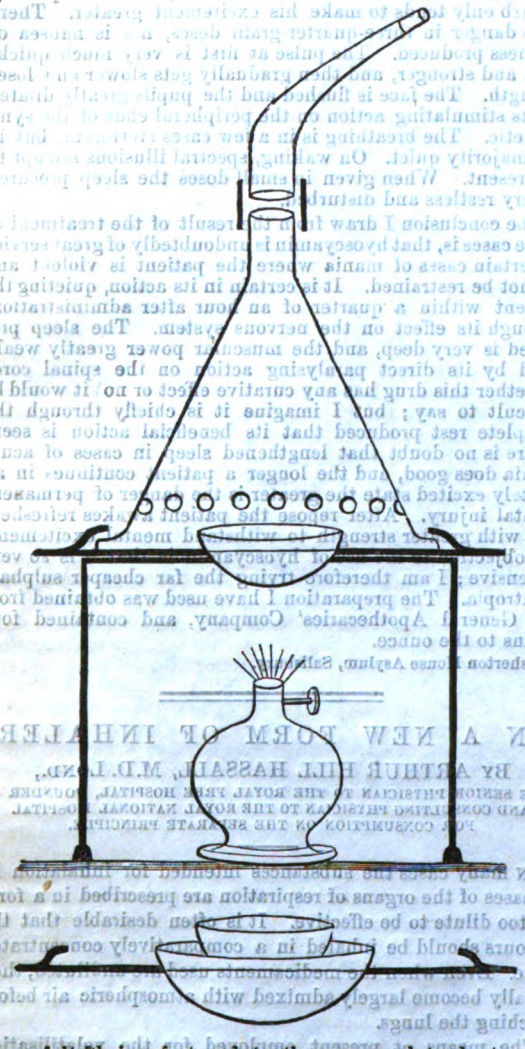
CASE 6.—B. P——, male, aged fifty. Not epileptic. A noisy, troublesome patient at times; broke a couple of mirrors, and attacked the attendants. Placed in seclusion. Ordered three-quarters of a grain of hyoscyamin, causing deep sleep. Awoke in the morning quiet. Allowed out.

It is, I think, the better plan to give a large dose at once than to administer smaller ones at intervals; for in the cases which are most benefited by this drug the difficulty is to get the patient to take more than one dose, and to frequently disturb only tends to make his excitement greater. There is no danger in three-quarter-grain doses, nor is nausea or sickness produced. The pulse at first is very much quickened and stronger, and then gradually gets slower and loses strength. The face is flushed and the pupils greatly dilated by its stimulating action on the peripheral ends of the sympathetic. The breathing is in a few cases stertorous, but in the majority quiet. On waking, spectral illusions are apt to be present. When given in small doses the sleep procured is very restless and disturbed.

The conclusion I draw from the result of the treatment of these cases is, that hyoscyamin is undoubtedly of great service in certain cases of mania where the patient is violent and cannot be restrained. It is certain in its action, quieting the patient within a quarter of an hour after administration, through its effect on the nervous system. The sleep produced is very deep, and the muscular power greatly weakened by its direct paralysing action on the spinal cord. Whether this drug has any curative effect or not it would be difficult to say; but I imagine it is chiefly through the complete rest produced that its beneficial action is seen. There is no doubt that lengthened sleep in cases of acute mania does good, and the longer a patient continues in an acutely excited state the greater is the danger of permanent mental injury. After repose the patient awakes refreshed, and with greater strength to withstand mental excitement. An objection to the use of hyoscyamin is that it is so very expensive; I am therefore trying the far cheaper sulphate of atropia. The preparation I have used was obtained from the General Apothecaries' Company, and contained four grains to the ounce.

Fisherton House Asylum, Salisbury.

ON A NEW FORM OF INHALER.



By ARTHUR HILL HASSALL, M.D. Lond.,
LATE SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL, FOUNDER OF AND CONSULTING PHYSICIAN TO THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION ON THE SEPARATE PRINCIPLE.

IN many cases the substances intended for inhalation in diseases of the organs of respiration are prescribed in a form far too dilute to be effective. It is often desirable that the vapours should be inhaled in a comparatively concentrated state. Even when the medicaments used are undiluted, they usually become largely admixed with atmospheric air before reaching the lungs.

The means at present employed for the volatilisation and inhalation in a concentrated form of the vapours of certain substances are often very defective. Thus iodine and carbolic acid are sometimes vaporised from a porcelain or metal plate placed near the patient; in this way the greater part of the fumes are lost in the air of the apartment, and the small portion really inhaled is diluted many thousand times. I have therefore devised a very simple apparatus for the accomplishment of the object desired. Its several parts are shown in the subjoined figure. It is suited alike for solids and liquids; and when an increase of temperature above that of the air is required, this is obtained by applying the lamp either directly to the capsule containing the substance or through the medium of the small water bath. One great recommendation of the apparatus is its absolute cleanliness. There is no probability, unless it is used in the most careless way, of its becoming contaminated with bacilli, and hence there is no risk of infection or re-infection, such as may happen when flexible tubes and mouth-pieces enter into the structure of the apparatus employed, and especially when more than one person makes use of such an inhaler. Such contingency constitutes a real danger, and one not usually realised.

The figures almost explain themselves, yet it may be well to give a brief general description. The apparatus

consists of a small spirit lamp, furnished with a fine rack, so that the flame can be nicely adjusted; a quadrangular stand; two pieces of copper sheeting, with a central aperture in each; a small copper water-bath; two small porcelain dishes; a funnel of glass or other suitable material, furnished with openings below for the admission of air; and a glass mouth-piece, which may be used or not, as may be required. The funnel should turn up at the bottom, so as to

allow of its being fastened to the copper plates by two or three simple springs. This apparatus is specially suited for the vaporisation of carbolic acid, creasote, iodine, thymol, eucalyptol, pine oil, and many other substances. The porcelain capsules should have a diameter of 1¾ in.; the water bath 2¾ in.; the base of the funnel 3½ in.; and the length of the mouth-piece should be about 4 in.

San Remo.

REPORT OF A CASE OF FIBROID UTERINE TUMOUR.

OPERATION; EXTIRPATION OF UTERUS; RECOVERY.

By JAMES DODD SWALLOW, M.D., M.R.C.S.

MRS. J. W——, aged thirty-seven, resides in the country. She was married eighteen months ago, and shortly afterwards began to notice enlargement of the abdomen, which during the last eight or ten months has become very marked, her general health being fairly good. The catamenia have been profuse, and she has lately become very thin and emaciated. During the last three months she has had pain in the right iliac region, much increased by walking or standing. In the early part of July last she came to London for advice. On examination, I found the abdomen was distended to about the size of the seventh month of pregnancy, and that it contained a large, solid, morbid growth. The outlines of the uterus could be easily defined; it extended upwards to within an inch and a half of the ensiform cartilage, and was perfectly movable, hard, and non-fluctuating. In each iliac region could be felt a mass of about the size of a small cricket-ball. Each of these was movable, and appeared to be either an independent growth or to be attached to the principal tumour by a peduncle. On examination per vaginam, the os uteri was found to be drawn up and tilted over to the right side; the sound passed with difficulty five inches; the uterus was quite movable. The diagnosis arrived at was fibroid tumour of the uterus, with two secondary tumours, one in each iliac region. In consultation with Mr. Sydney Jones (who after careful examination confirmed this diagnosis), removal was decided upon, and this mainly in consequence of the rapidly increasing growth, the excessive monthly loss, the pain, and the progressive emaciation of the patient. On July 13th, the patient being placed under ether by Mr. Osborn of St. Thomas's Hospital, Mr. Sydney Jones operated, antiseptic precautions being carefully observed. The abdominal cavity was easily reached by an incision about five or six inches long. Great care was required at the lower part of the incision, on account of the bladder being drawn up considerably by the growth of the tumour (the base of the bladder was drawn up fully two inches above the os pubis). The bladder was dissected off the front of the uterus, and the lateral connexions of the tumour were divided, after ligaturing with double thread. The neck of the uterus below the large fibroid was elongated, and formed a comparatively narrow peduncle above the os. The enlarged uterus, with five or six pedunculated fibroids, and the ovaries, were tilted forwards out of the abdomen, and the neck was transfixed by a needle carrying a double thread of Belgian twist. The threads were firmly tied, one on each side, and the neck of the uterus divided just above the os. Another strong silk ligature was made to surround the peduncle at the situation of the double thread. Very little blood was lost during the operation. The edges of the abdominal wound were brought together by silk and catgut sutures alternately, and all was securely packed with antiseptic dressings. After the operation a subcutaneous injection of morphia was given, and the patient put to bed. The sickness continued for twenty-four hours. She was ordered to suck ice at intervals, and morphia was injected night and morning; catheterism every eight hours. This treatment was continued until July 16th, three days after the operation, when my note is as follows:—The patient is now free from sickness. Temperature (10 A.M.) 100°; pulse 90. Sleeps well, is cheerful, and has had no pain. There is a bloody discharge from the vagina; no tympanites. Ordered to take a teaspoonful of iced milk frequently, and to suck ice.—18th: The milk, having produced sickness, to be discontinued, and ice alone to be sucked. — 19th: No sickness. Temperature (10 A.M.) 100·2°; pulse 94. Has passed a good night. Ordered to have a teaspoonful of Brand's extract of beef occasionally, and to continue the ice and morphia injections night and morning.—21st: The patient is doing well. Temperature (10 A.M.) 101°; pulse 100. The first dressings and the silk sutures were removed; wound almost healed; walls of abdomen supported by broad straps of plaster. The bowels having been cleared by enemata, she was allowed to take beef-tea, milk, and three ounces of port wine during the day. The patient complains of no pain, sleeps without morphia, and says she feels quite well. During the next few days her progress was somewhat interfered with by vomiting and inability to take much nourishment. — 28th (fifteen days after the operation): Dressings removed; wound quite dry, except here and there; the patient sleeps well, and takes nourishment; bowels relieved daily; allowed to sit up for an hour.—30th: Some swelling of the foot and calf of the leg; temperature and pulse normal.—Aug. 3rd (three weeks after the operation): Except some swelling of the left foot and calf, the patient is well; takes food, wine, and stout with relish. To wear a well-fitting belt.

The points of special interest in this case appear to be: first, the great ease with which the tumour was exposed, detached from surrounding parts, and removed (as after dissecting the bladder from the front of the uterus, and separating the lateral connexions, the tumour was easily

Digitized by Google

drawn forwards from the abdomen, and a comparatively narrow peduncle had to be dealt with); secondly, the patient being kept under the influence of morphia; and thirdly, being allowed to take scarcely anything but ice for seven or eight days after the operation.

Clapham, S.W.

A CASE OF
DIABETES TREATED BY PILOCARPINE.

BY T. CAWLEY EAGER, L.R.C.P. ED., M.R.C.S.

T. H——, a prison warder, aged forty-three years, first consulted me on Jan. 1st, 1882. I had known the patient for some years, and was much struck by his altered appearance. When I last saw him, some six or eight months before, he was a healthy robust looking man, but he had become pale and wasted and had a tired and worn look. His previous history was good till November, 1881, when he was under treatment for an abscess in the right hand, which was followed by boils, more or less severe in character, about the body generally, and since that time he had been getting thinner and weaker. His symptoms in January, 1882, were a *feeling* of failing health, great thirst, and a frequent passage of urine; this disturbed him several times during the night. The appetite had been better than usual, but the food seemed to do him no good, for he had been constantly growing thinner, his weight now being 179 lb., against the normal weight of 222 lb. On questioning him more closely, he told me he was passing sixteen pints of urine in the twenty-four hours, that he had entirely lost all sexual appetite and power, and that he felt utterly weary and worn out; in fact, the man's appearance, as he lolled in a chair, with rounded shoulders and drooping head, quite bore out his statement. The skin was dry and harsh, the tongue red and glazed, the mouth dry and clammy, the gums and lips covered with sticky mucus, and the bowels confined; the sight, however, was not affected in any way, his vision being perfect. On examining the urine, I found the specific gravity to be 1040, and containing, as shown by Trommer's test and subsequently verified by Roberts' fermentation method, an abundance of sugar.

I ordered a diet of butcher's meat, poultry, and fish; green vegetables, such as cabbage, spinach, and cauliflower; cheese; eggs, especially the white of the egg; Van Abbot's gluten bread, with or without butter; tea, with a little milk or cream, and sweetened with glycerine if necessary; seltzer, soda, or potash water, with five ounces of whisky or brandy; and also claret. The medicinal treatment was as follows:—One-twentieth of a grain of hydrochlorate of pilocarpine and one grain of sulphate of potash, to be placed dry on the tongue three times a day; five grains of pepsina porci and twenty minims of dilute hydrochloric acid, in an ounce of peppermint water, to be taken three times a day. A soap-and-water enema to be used daily if the bowels are not opened.

Under this treatment the patient began quickly to improve; within a month there was a marked lessening of the quantity of the urine passed, and of the amount of sugar it contained, and also a gain of 7 lb. in weight. The pilocarpine powders were taken regularly for six months, and the pepsine mixture for nine months, when both were stopped and no further medicines were given. The patient was seen at gradually lengthening intervals until July, 1883. The diet had been persevered with until this date, when the gluten bread was discontinued, brown bread or crusts of a well-baked loaf being substituted. Cocoa was allowed, as also a few turnips and carrots, and if the symptoms did not return in a month potatoes in moderation were to be added; but no sugar was permitted to be taken. Up to March of the present year the improvement had continued, the weight being then 207 lb., and the urine normal both in quantity and quality; all harshness of the skin had disappeared, the sexual appetite and power had returned, and to all intents and purposes the man was well.

Remarks.—This case at the commencement appeared to be a most unfavourable one; indeed, I did not hesitate to tell the patient that I thought most gravely of his condition. Fortunately for him he was most conscientious in carrying out the course of treatment I advised him to pursue, and did not relax it except when I gave him permission. It will be observed that no preparation of opium was given, for though codeia undoubtedly has the power of reducing the quantity of urine, it does so very frequently at the expense of the appetite, for the patient will often be found to become weaker and lose weight by its continuance. My reason for pursuing the treatment I adopted was by means of the pilocarpine to relieve thirst by promoting salivation, and thus diminish the quantity of urine, thereby increasing the weight and hence restoring bodily vigour. One of our great troubles in diabetes is the difficulty in getting patients to persevere in a treatment so monotonous, so that one rarely has a chance of recording an apparent recovery, especially in cases where there is so much loss of weight and such a quantity of sugar excreted.

Woking, Surrey.

MISPLACEMENTS OF THE UTERUS.

BY CHARLES E. FITZGERALD, M.D. ST. AND., &c.

AT the present moment, when so great a diversity of opinion exists among our leading gynæcologists as to the importance or non-importance of misplacements of the uterus, it is useful to appeal from theory to fact; and with this object it may not be uninteresting to cite the following two cases, as tending to show that some misplacements of the womb are not always devoid of serious or even disastrous consequences.

C. E——, aged twenty-seven years, unmarried. The patient had attempted suicide by strangulation. On my arrival I found her face much swollen, and of a livid bluish-red, with numerous petechiæ and patches of extravasated blood, and the conjunctival vessels ruptured—in fact, the usual appearances of strangulation. There was intense despondency and hysterical weeping, and a firm determination to refuse food. The tongue was foul, and the pulse rapid and compressible. The bowels were obstinately constipated, and the menses had been suppressed for six months. She expressed regret that she had been prevented from hanging herself, and exhibited great dislike to her mother, to whom she had been greatly attached. Her condition was one of profound melancholia. I ordered her a dose of calomel, and a brisk purge, to be followed by a mixture of sodium bromide and henbane, and compelled her to swallow some strong beef-tea. At my next visit I found her only very slightly better, although the medicine had acted well. As she still obstinately refused to take food, I again forced some beef-tea down her throat. I expressed an opinion that the uterus might possibly be at fault, and at her mother's request made a vaginal examination. I found a condition of extreme retroflexion and retroversion, the fundus being very low down and pressing on the rectum. With some difficulty I introduced a sound and replaced the uterus (the patient struggling and howling like a wild animal meanwhile), and kept it in place with a vulcanite Hodge pessary. Immediately the womb was in its place the patient became calm and quiet. The next day I found her quite sensible, calm, and smiling, though the face was still much swollen and congested. The menstrual flow had occurred in the night. She was taking her food readily, and was again affectionate to her mother. She told me she thought she "must have been mad to have behaved as she had done." This young lady remained perfectly well for more than two months, at the end of which time she came again to me complaining of depression of spirits, malaise, &c. I found the uterus again somewhat retroflexed, and that she required a rather longer pessary. She has continued well ever since.

F. G——, aged twenty-two, unmarried. When first seen she was suffering from profuse menorrhagia, which had persisted more or less, and with scarcely a day's intermission, for eighteen months. The pulse was weak and rapid. There were great prostration and general weakness. The face and skin were blanched, and the expression anxious. The gums and lips were bloodless, and the patient could not leave the horizontal position without fainting. She was ordered one-drachm doses of the liquid extract of viburnum opulus, and ice externally and internally, and by these means the hæmorrhage was, with difficulty, checked. On the third day I examined her, and found the uterus retroflexed at an acute angle, very much congested, and low down in the pelvis. I at once rectified the position, and introduced a

Digitized by Google

Hodge pessary, which retained the organ in position. The hæmorrhage ceased almost immediately, and did not return until the next menstrual period, and was then unusually profuse, during which she took first ergot and then tincture of iron. I kept this patient under observation for one more period, which was, however, quite natural. I then withdrew the pessary, and she returned home and has kept well ever since. This young lady had been under treatment for many months before I saw her, and had taken large quantities of iron, gallic acid, lead, ergot, &c., without effect.

Although I could quote many cases from my note-book where misplacements of the womb have produced grave symptoms, and which have rapidly subsided when the organ has been replaced and supported by a well-fitting pessary, I should not wish it to be thought that I overrate the importance of uterine misplacements. On the contrary, I believe that in many cases they exist without causing any manifest inconvenience; and I am of opinion that all the manipulations, injections, pessaries, &c., which are sometimes thought necessary in the treatment of these cases are worse than useless, and only tend to aggravate and encourage that morbid and self-conscious frame of mind which is so often found in women suffering from womb complaints. That there are, on the other hand, cases of misplacement requiring active mechanical and other treatment I do not for a moment doubt, and I think this is conclusively proved by the cases above quoted. It is, after all, a question of judgment; for while some cases should be judiciously treated, others should be as judiciously left alone. When there is no active congestion of the uterus due to obstructed circulation, no menorrhagia, no severe pain, no injurious consequences from pressure on the rectum or bladder, no bar to conception—in fact, merely a flexion due to relaxed ligaments and dependent on a condition of general weakness or ill-health, then the uterus may safely be left alone. When, however, the reverse conditions exist, then we should be deterred by no sentiment—or, worse still, by no fashion—from active and appropriate treatment.

WEST LONDON HOSPITAL.

RUPTURE OF THE TEGUMENTARY AND OTHER COVERINGS OF AN INGUINAL HERNIA THROUGH THE CICATRIX OF AN OLD INCISION FOR THE RELIEF OF STRANGULATION; PROTRUSION OF MORE THAN THREE FEET OF INTESTINES; REDUCTION; RECOVERY; REMARKS.

(Under the care of Mr. KEETLEY).

FOR the notes of this rare and remarkable case we are indebted to Mr. W. Milne Anderson, M.B., C.M., house-surgeon.

J. H——, a coal carter, aged fifty-six, was admitted on April 1st, 1884. He had suffered from a left inguinal hernia for twenty years, and was operated on for strangulation about five years ago. About 3 P.M. on April 1st, he was jumping off his cart, when he suddenly felt something give way, and on examining himself found part of his intestines protruding from the seat of his rupture. He left his cart in charge of a policeman, and, supporting the gut with his hands, walked a quarter of a mile to see a surgeon, who wrapped a piece of lint round the part and ordered him to go off to the hospital at once. On leaving the surgery he walked back to the place where he left his waggon, and then took a cab to the hospital.

State on admission.—On examination, his clothes and skin were found to be covered with coal dust. Lying on his abdomen were three coils of small intestine, slightly reddened and congested. Each coil was fully a foot in length. The pulse was good, and the patient did not appear to be suffering much pain. He was immediately put under ether, and Mr. Keetley, who happened to be in the hospital at the time, proceeded to operate. The surrounding parts were washed, and pieces of lint soaked in boracic lotion placed in the abdomen and round about the rupture. Each fold of gut was carefully sponged with boracic acid lotion, and then protected with a piece of lint soaked in the same. When the bowel was thoroughly cleansed, an attempt was made to reduce it, but this was found to be impossible until the rent had been enlarged a little and the ring nicked. Considerable manipulation was required to return so great a length of bowel into the abdominal cavity. The wound was a clean tear about two inches long, and seemed to be through the site of the old incision. The skin around the rent was shaved and thoroughly washed with a solution of perchloride of mercury. The neck of the sac was stitched up with catgut, as also were the pillars of the ring. An attempt was made to separate the sac, but unsuccessfully, owing to the intimate blending of all the coverings of the hernia. The opposite surfaces were therefore brought together by deep sutures and buttons. A drainage-tube was inserted, and the skin brought together with silver wire. An antiseptic dressing was applied, a pad of iodoform gauze being next the wound. The patient was put to bed and an opiate given. He was allowed nothing save ice to suck for twenty-four hours.

He passed a good night, was free from pain, and had no sickness. Next morning the temperature was 100·6°. About 4 P.M. a wineglassful of milk was ordered every two hours in ice. Evening temperature 100°. On the 3rd patient said he felt comfortable. Temperature 99°. The bowels had been opened freely. A nutrient enema was given every six hours. The evening temperature was 100°. On the 5th, as he complained of feeling uncomfortable after enemata, they were left off, and low diet ordered. Evening temperature 100°. On the 6th he passed a restless night, the temperature on the morning of the 7th being 100°. The wound was dressed for the first time. There was a slight discharge of pus along the deep button sutures, which were removed, as also were the superficial ones, and the drainage-tube was shortened. He passed a good night. On the 10th the temperature was 100°. The wound was dressed again. There was a considerable discharge of pus from the site of the button sutures. Several incisions were made, and three small drainage-tubes inserted.

From this time the wound was dressed daily, the temperature varying between 99° and 101°. On April 22nd the temperature rose to 102°. The wound was injected daily with a lotion of sulphate of zinc and subnitrate of bismuth. The discharge became less, but, the temperature still keeping about 100°, the sinuses were slit up, scraped, and packed with iodoform gauze on May 9th. After this the temperature fell to normal, the wound gradually healed, and he left the hospital with his hernia radically cured on June 11th.

Remarks by Mr. KEETLEY.—This case is interesting from (1) the rarity of the accident, (2) the length of time during which many feet of intestine remained in contact with the air and with the patient's grimy trousers and shirt without any peritonitis resulting, and (3) the contrasted behaviour of the parts internal and external to the hernial opening respectively. The only similar case with which I am acquainted was that of a lady of whom I heard the late Mr. Holmes Coote relate that the coverings of her umbilical hernia ruptured spontaneously while she was returning from a dinner at Richmond. Mr. Coote was sent for to her house in town, and replaced the escaped intestines. The patient recovered completely. Of course there have been many cases of recovery after the escape of intestine through a wound. The case above recorded would tend to show that the peritoneum is either not very susceptible to ordinary as distinguished from specific septic infection, or that at least it is easily disinfected. That a smooth thin membrane like the peritoneum should be much more easily and speedily asepticised than the thick irregular skin crowded with glands, and in the pubic region studded with hair follicles, is what would be naturally expected; and I was not much surprised to see the extra-peritoneal wound suppurate. The sutures of the neck of the sac and of the ring completely isolated and protected the abdominal cavity and its contents, which were never affected by the suppuration in and about the old sac. Considering the great length of intestine which had escaped (at first glance it looked as though there must be more outside than inside the abdomen), the process of reduction

Digitized by Google

was easy. But one end was passed back far more easily than the other, and almost all the escaped intestine was passed back in one direction, one inch after another being pushed in by the forefinger or the fingers of one hand and kept in by those of the other. Boracic lotion was used for the cleaning and aspepticising of the intestine, because there was reason to expect that the cleaning and replacement would occupy a long time, for which reason carbolic lotion was objectionable both on account of its irritating qualities and the danger of poisoning; but the extra-abdominal parts where the suppuration eventually took place were treated both with carbolic and corrosive sublimate lotion (1 in 1000).

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

BUFFER ACCIDENT; DEATH; NECROPSY, REVEALING TWO RUPTURES OF THE DIAPHRAGM AND PROTRUSION OF THE RIGHT LOBE OF THE LIVER, THE SPLEEN, AND THE STOMACH INTO THE THORACIC CAVITY; LACERATION OF SPLEEN AND KIDNEYS.

(Under the care of Mr. KOUGH.)

FOR the following notes we are indebted to Mr. J. W. Batterham, B.S. Lond., house-surgeon.

J. J——, aged twenty-six, while at work as a "shunter" on July 24th, 1884, at 12·30 A.M., was crushed between a railway engine and the buffer of a "goods" van. When admitted into the hospital half-an-hour after the accident, he was conscious, and complained of thirst and of great pain over the lower part of the abdomen. The skin generally was cold and pallid but the face was of a dusky hue. The pulse was just perceptible. No fracture of the ribs or pelvis was discovered; the abdominal walls were extremely retracted; there was dulness on percussion over the hypogastrium and the flanks. A few drops of bloody urine were drawn off by catheter. The patient had no desire to pass urine. There was no vomiting or retching, and only once did the patient complain of nausea. He became rapidly weaker, and died about two hours after admission.

Necropsy, thirty-six hours after death.—A few abrasions were noticed on the trunk and thighs. There was very little post-mortem congestion of the dependent parts, the skin being remarkably exsanguine. Abundant punctiform ecchymoses were noticed over the upper sternal region, neck, and face; these ecchymoses ended abruptly about the middle of the forehead, being absent over the part presumably covered by the cap. There was a slight effusion of blood beneath the skin of the eyelids, as well as beneath the ocular and palpebral conjunction. On opening the thorax about two pints of blood escaped from the pleural cavities. The heart, which contained very little blood, was normal in appearance. No ecchymosis of the pericardium or endocardium was noticed. The lungs were shrunken, crepitant, and bloodless. On removing the thoracic viscera, subpleural extravasations were seen about the roots of both lungs and beneath the right costal pleura. Two extensive lacerations of the diaphragm were now apparent, one about five or six inches long, extending across the right division of the central tendon; and a second, about an inch less in extent, extending through the muscular fibres behind the left division of the tendinous portion. Protruding through the rent on the right side was the posterior half of the right lobe of the liver. This portion of the liver was devoid of peritoneal covering, which appeared to have been reflected from it as it was thrust through the ruptured diaphragm. On the under surface of the right lobe was a small laceration an inch long and half an inch deep. Through the rent on the left side of the diaphragm had passed the spleen and the stomach. The latter, which was partially distended by fluid food, was intact. The left kidney was found lying in the rent. Very little blood was found free in the abdominal cavity, but there was extensive retro-peritoneal extravasation around the duodenum and kidneys. Both kidneys and spleen, more especially the former, presented lacerations extending in a radiate manner from the hilus. The pancreas was not lacerated, but presented several interstitial hæmorrhages. The intestines, which were almost empty, were unruptured, and no part except the duodenum showed any signs of bruising. The bladder was intact, and contained about two ounces of bloody urine.

Reviews and Notices of Books.

Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners. By H. MACNAUGHTON JONES, M.D. Pp. 410. London: Baillière. 1884.

THE task which the author has set himself is an exceptionally difficult one; it has not, in our judgment, been yet satisfactorily accomplished, and the work before us forms no exception to the rule. Dr. Jones does not seem to have laid out his work so as to apportion a suitable space to each subject, some parts being treated more or less at length and with long quotations, while other important questions are reduced to mere lists. Again, possibly out of regard for sensitive feelings, essentially contradictory opinions are endorsed, the author's own views being thereby rendered inscrutable. He indulges in spirited denunciation of inventors of pessaries, and yet describes them and figures them by the score. He repeatedly asserts that this or that operation will not be described, as it is unsuitable for the general practitioner, and yet, for example, says such things as the following: "Simple incision of the lower part of the cervix has frequently to be resorted to, and is a step that must constantly fall to the lot of every practitioner"; the application of nitric acid to the cavity of the uterus "is a simple step that any intelligent practitioner should be able to carry out." We also quote the following: "In young anæmic or chlorotic girls a vaginal examination is, as a rule, not necessary." (We should think not, indeed!) "Only when, from other symptoms, we are led to suspect some inflammatory condition, or a version or flexion, is a digital examination called for." And this in spite of the fact that 75 per cent. of all nulliparous women have anteverted or anteflexed uteri! Dr. Duncan is said to associate spasmodic dysmenorrhœa with versions and flexions—a statement which we leave to that gentleman, who is quite capable of fighting his own battles. The figures are not a redeeming feature, and some of them, representing nude women in various postures, quite unnecessary. But we cannot omit to mention, in conclusion, that the author does really commit himself to an opinion adverse to intra-uterine stems; and that the preface contains several unimpeachable medico-ethical sentiments. The glairy transparent cervical plug once again figures as the enemy of the human race; which reminds us of the dictum of the American orator with regard to woman—that "Had it not been for female woman, few of us would be here at the present time."

Poisons; their Effects and Detection. A Manual for the use of Analytical Chemists and Experts. By ALEXANDER WYNTER BLYTH, M.R.C.S., F.C.S., Public Analyst for the County of Devon, and Medical Officer of Health and Public Analyst for St. Marylebone. London: Charles Griffin and Co. 1884.

THIS is a companion volume to the author's well-known work on Foods, and they together constitute a new edition of his Practical Chemistry. The reason for the change of title is obvious. The present appellation is distinctive, and avoids the possibility of confusion with works of a different scope and character, which might with equal propriety be classed under the head of Practical Chemistry. The new volume, like its predecessor, opens with an historical account of the subject, an excellent *résumé* being given of old poison lore. This is followed by a number of useful tables, one of them being devoted to an analysis of 1000 cases of suicide which occurred in England between the years 1871 and 1880. Opium, it appears, is in this country responsible for over 40 per cent. of the total deaths from all kinds of poisons. This is a higher percentage than prevails in

Digitized by Google

any other European nation. In France poisoning by opium and morphia accounts for only about 1 per cent., whilst in Denmark, Sweden, Switzerland, and Germany the proportion is equally low. Our high mortality, says Mr. Wynter Blyth, arises in great measure from the pernicious practice, both of the hard-working English mother and the baby-farmer, of giving infants "soothing syrups," "infants' friends," "infants' preservatives," "nurses' drops," and the like, to allay restlessness, and keep them during the greater part of their existence asleep. A long list is given of patent medicines containing opium, from which it appears that in many cases the proportion of the active drug is much higher than in any pharmaceutical preparation. A good and clear account is given of the ptomaines, or cadaveric alkaloids, a subject which has of late attracted much attention both here and abroad. The various kinds of snake-poison are dealt with in an able manner, much of the information being evidently the result of personal observation. The mydriatic alkaloids are fully discussed in all their bearings, and their antagonists, physostigmine, pilocarpine, and muscarine, receive due notice. The information is, as a rule, up to date, care having been taken to include several of the newer remedial agents, such as guebracho, and its active principles, aspedosperminé and guebrachine. In some cases the author has unfortunately overlooked important papers, and in one or two instances has omitted nearly all reference to the physiological action of the drug. The chapter on the Treatment of Cases of Poisoning is poor, and requires careful revision; but taking the work as a whole, it may be said to be worthy of the author's high reputation.

A Treatise on Chemistry. By H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S., Professors of Chemistry in the Victoria University, Owens College, Manchester. Vol. III. Part 2. London: Macmillan and Co. 1884.

The Principles of Theoretical Chemistry, with special reference to the Constitution of Chemical Compounds. By IRA REMSEN, M.D., Ph.D., Professor of Chemistry in the John Hopkins University. Second Edition. London: Baillière, Tindall, and Cox. 1884.

A Short Text-book of Inorganic Chemistry. By Dr. HERMAN KOLBE, Professor of Chemistry in the University of Leipzig. Translated and edited by T. S. HUMPIDGE, Ph.D., B.Sc.Lond., Professor of Chemistry and Physics in the University College of Wales, Aberystwyth. London: Longmans and Co. 1884.

A Text-book of Inorganic Chemistry. By Professor VICTOR VON RICHTER, of the University of Breslau. Authorised Translation of the Third German Edition, by EDGAR F. SMITH, A.M., Ph.D., Professor of Chemistry in Wittenberg College, Springfield, Ohio. London: Henry Kimpton. 1884.

THE fifth volume of Roscoe and Schorlemmer's treatise continues, but by no means finishes, the history of organic chemistry. It would seem, indeed, as if two more volumes would be required, and we trust they will appear with as little delay as possible, for a complete treatise on organic chemistry is very much wanted. Among the groups described in the present volume may be noticed as particularly important to our readers those which include oxalic, lactic, succinic, malic, tartaric, citric, and oleic acids, the uric series, the glycerides, the drying oils, and, above all, the carbohydrates, which are excellently arranged and described. The high merit of the previous volumes is fully maintained, the historical sketches have been prepared with great care, and the bibliography is exceedingly rich. Everyone interested in chemistry will want the book, and all will feel grateful for it.

There is really very little to say about the three elementary text-books whose titles are given above. Each possesses great merit, and each would be an absolute treasure if there were not already so many of the same kind in existence.

Professor Remsen's little book is a second edition, which proves that in America, at any rate, its value has been recognised. The second part, dealing with the constitution of chemical compounds, is, we think, the best.

Professor Kolbe has given to the German and Professor Humpidge to the English student a guide in which theory and description are well balanced. It is intended as an aid to students attending a course of lectures; and the author, in his preface, gives some wise and opportune remarks, the results of great experience, on the value of lectures and their limits of usefulness. He says: "A necessary condition for using a text-book of chemistry successfully is attention and continuous attendance at the lectures. Students in Arts who have not regularly attended a course of lectures may be able to read up afterwards what they have missed; but a lecture which has not been attended by a student of chemistry cannot be made up by mere reading; neither the notes of the lectures by other students, which ought to be extremely few, nor a text-book, can serve as a substitute for what has not been heard. The chemist has to learn, not by reading nor by hearing alone, but by hearing and seeing. A person who has not *seen* the phenomena produced by the union of oxygen and hydrogen, for example, can have no clear conception of them, nor of the chemical change that accompanies them. Nothing is more foolish than the opinion which I have often heard from young medical students that chemistry can be studied from books alone [we presume the translator means books *only*], like other subjects; that facts which are learnt by heart can take the place of general principles only partially understood." With this, and with much that follows, we entirely agree. The general principles of the science can only be taught by lectures aided by reading, for no student can verify fundamental laws by experiment. In fact, to quote Professor Kolbe once more: "To enumerate many chemical facts loads the memory with ballast, and tends to learning by rote instead of clear perception and after-thought." It will be seen from the above extracts that the translation is not very elegant. It appears, however, to be on the whole clear and accurate.

Professor von Richter's manual has not fared quite so well in the hands of the translator. Some glaring errors disfigure the English version—notably, the repeated use of the words methyl and ethyl, instead of methane and ethane, on pages 142–144. The book is, however, in several respects original, and we note with special approval the section on crystallography, and the account of, and frequent allusions to, thermochemistry, a branch of the science much neglected in English books, but of rapidly increasing importance. We are sorry to see that both Professor Remsen and Professor Kolbe attribute the interesting periodic law of atomic weights to Mendelejeff, instead of to John Newlands, who was its real discoverer.

The London Water-supply—Past, Present, and Future. By G. PHILLIPS BEVAN, F.S.S. London: Edward Stanford.

AT a time when changes in the organisation by which London is supplied with water are being so much discussed, this little work has an interest beyond that which it would otherwise secure on its own merits, for in a compact form it gives an account of the ancient and modern methods by which the metropolis has been supplied, together with many important and useful details as to the existing water companies, concerning whose operations and proceedings it is so important that Londoners should be well informed. Whilst our London supply tends to diminish, the demand for water is on the increase, and hence the author considers the feasibility of procuring the needed further supply—first, from the Thames basin, and, secondly, by means of one or other of the north country schemes that have been advocated. Whatever steps may be taken in the direction of

Digitized by Google

purification of sewage, the fact remains that the sewage of nearly a million and a half of people has, after being submitted to certain processes, to find its way into the Thames valley, and hence Mr. Bevan describes in detail the several alternative schemes of supply, feeling confident that to one of these London will ere long have to turn.

SOME INTERNATIONAL HEALTH LITERATURE.

London: William Clowes and Sons.

Accidental Injuries. By JAMES CANTLIE, F.R.C.S.—This handbook is intended as a guide from which the public may learn how to render efficient aid at the moment of injury. The book is illustrated with good woodcuts, and has an index easy of reference. The instructions given are very excellent, and conveyed in language as free as possible from technicality.

Dress. By E. W. GODWIN, F.S.A.—The method on which this book is constructed is the historical; the history of dress is said to be curiously parallel with that of architecture. "As speaking involves poetry and music, as architecture involves painting and sculpture, so dressing involves in principle all these." The dress of civilised nations may be broadly divided into two great classes, the loose and the tight. This primary distinction is, no doubt, owing to climate. The highest type of the first class is seen in the Greek chiton and himation, as represented in sculpture and on vases, of 450-350 B.C. The highest type of the second is found in the effigies and paintings of England and France about 1250 A.D. This book deals chiefly with the artistic aspect of dress, and contains a large amount of information, with sixty-eight capital illustrations.

Athletics. By Rev. E. WARRE, M.A.—This is a very good little book indeed; everyone should read it. We shall content ourselves with quoting a sentence from the chapter on Advice to Reading Men. To all who are working for an examination the author says, "Your brain, in order that it may do its work, will require a continual supply, and that a large supply, of good arterial blood. What are you doing about your heart and lungs?"

Alcoholic Drinks. By JOHN THUDICHUM, M.D. A large amount of information is brought together in this handbook; but the reader does not meet with much encouragement to proceed with his subject, owing mainly to the uninteresting manner in which the matter is presented. We are in agreement with the sense of the author's last paragraph, which is to the effect that liqueurs are frequently offered at a price many times their value.

Infectious Disease. By SHIRLEY MURPHY.—The origin, behaviour, and means of prevention of infectious disease is here treated in a popular manner with great success. We hope that the book will be widely read, not only from a desire to further the diffusion of useful knowledge, but also from a belief that such diffusion would tend to lighten the task of the doctor, who has often to battle with the passive resistance of the friends of his patients in dealing with cases of infectious disease. Moreover, the dangers from contagion which constantly surround the individual cannot be better averted than by the personal possession of information concerning them.

Diet in relation to Health and Work. By A. W. BLYTH, M.R.C.S.—The arrangement of this book is systematic. The material is conveyed in plain language. A great deal of instruction is brought together in the small compass of ninety-two pages. Five tables of reference showing the percentage composition of various articles of diet are not the least valuable part of the work. The chapter on the Principles of Diet is likely to prove interesting to a large section of readers of popular works.

Healthy Nurseries and Bedrooms. By Mrs. GLADSTONE.—This brief essay will assuredly be read with profit by all who have watch and ward of children. In a very modest preface the authoress claims for the work but little originality, having thought it well to bring together in a convenient form information derived from many trustworthy sources. In this she has succeeded admirably. Dr. Champneys has given his aid in the chapter on the Lying-in Room.

New Inventions.

THE ATMONEMETOR, OR SPRAY-PRODUCER.

THE apparatus figured below, introduced by Dr. Wright of Old Burlington-street, consists of a bottle to which is attached a syringe. This is worked by pressure of the thumb on a spiral spring fixed round a piston-rod. The air thus driven displaces a small portion of the fluid contents of the bottle, and forces it along a horizontal tube, at the end of which it is discharged through very minute orifices, and is distributed in finely divided spray. Though suitable for

other purposes, the instrument is primarily intended for use in throat diseases, and to facilitate employment in these cases the tube is furnished with a plate beneath, which serves as a tongue depressor. The Atmonemetor is a very convenient instrument, as it can be held firmly and worked with one hand. In its construction, also, it is free from soft and perishable material, and is thus available in any climate. It is made by Messrs. Krohne and Sesemann.

"PHYSIOLOGY OF THE FEET."

To the Editor of THE LANCET.

SIR,—I am sorry to have misunderstood Mr. Ellis's remarks on the above subject, since it appears that we agree as to the facts, and differ only in our views of what ought to be. One should be cautious in accepting a theory which does not accord with daily experience. I must, therefore, hold my present opinion until it has been distinctly shown that untrained savages place the toes down first, not only when walking on stones or thorns, but also on smooth ground. Even then it would not follow that we ought to imitate them; our distant ancestors walked on all fours, but it has long ceased to be right to do so. The act of letting the heel gradually down from the toe and afterwards raising it complicates the act of walking in a way quite unnecessary under ordinary circumstances. If I have to walk among tin-tacks or the like, I certainly place the toes down first; but then I keep the heel off the ground entirely, finding it most comfortable to put down as little of the foot as possible.

I am, Sir, yours faithfully,

August 10th, 1884. FOSTER ALLEN.

THE POLLUTION OF THE WITHAM.—On the 6th inst. Mr. Harrison, an Inspector of the Local Government Board, held an inquiry with respect to an application by the Corporation of Lincoln for the consent of the Local Government Board to proceedings being taken against a firm of tanners for polluting the Upper Witham. After hearing evidence, the Commissioner said he thought it very desirable that the matter should be arranged, and after some discussion, it was decided to adjourn the inquiry until Oct. 1st, with a view to that course being taken.

THE LANCET.

LONDON: SATURDAY, AUGUST 16, 1884.

THE subject chosen by Dr. KIDD for his address before the meeting of the British Medical Association at Belfast—Puerperal Fever—is one, in whatever manner it be treated, or from whatever point of view examined, whose interest never fails; for the importance and value of the lives of its victims, the peculiar circumstances in which it makes its attacks, and the degree of uncertainty surrounding its cause and origin, together with the fear and loathing with which it is regarded, will always make it a subject of the greatest interest to the obstetrician and general practitioner. At all periods no little time and labour have been devoted to its study, but during recent years this study has been pursued with a method and a care never devoted to the subject in previous times; and the results obtained, though they have by no means fully cleared up the nature and mode of origin of the disease, yet have done much to further our knowledge of them, and, paradoxical as it may seem, much more towards their treatment, both preventive and curative.

The tendency of modern research has been to show that childbed fever is the result of septic infection; that there is no specific puerperal fever occurring epidemically, like small-pox and scarlet fever; that other fevers and the acute specific fevers may attack lying-in women and run their usual course, or become complicated by so-called puerperal fever or septicæmia; and that there are cases in which severe febrile symptoms may arise in consequence of the injuries sustained by the pelvic organs during labour, such fevers being independent of septic influences. Dr. KIDD appears to be at one with the majority of obstetricians with respect to much that is believed about these affections; but he discards the septicæmic and believes in the specific character of the fever, or of certain cases of it; and in his address at Belfast he brought forward some of the evidence upon which this view is based. In the brief time at his disposal it was impossible for him to marshal all the evidence at his command in support of his view; at the same time, fully aware of the tendency of modern research, he cannot have failed to produce some of the strongest and the most unanswerable evidence in his possession, with a view to stem the tide of modern error; and it is to this part of his address that we would more particularly direct attention.

This form he illustrates and describes under "epidemics" of puerperal fever. "In the case [epidemics] we have now to consider," he says, "the disease may manifest itself before labour has set in. It seizes great numbers at the same time; it observes cycles of development and decline, sometimes disappearing altogether for short or long periods; at its onset it proves fatal to almost all who are attacked by it; as it declines, it becomes more mild in its character, and many of those attacked recover." Then Dr. KIDD illustrates this statement by a case, and by the history of the outbreak of puerperal fever in Dublin in 1854–5, as given by the late Dr. MCCLINTOCK. In the case related by Dr. KIDD, fever set in before labour, and three days after labour diarrhœa, pain, and vomiting, with death on the sixth day. The case is too briefly recorded to define the illness preceding labour, but surely it does not follow that it was puerperal fever. It is well known that in the course of certain fevers pyæmia occurs, and the case reported by Dr. KIDD appears to be one of septic poisoning in the course of, and perhaps caused by, a febrile condition already present. This is a very different thing from puerperal fever setting in before labour. While considering this point, it should always be borne in mind that, whereas a surgical operation is not performed in the presence of fevers, labour not unfrequently sets in in the course of one of these diseases, and that a febrile state alone is sufficient to give rise to fetid lochia, a condition generally believed to play a very important part in the production of the fevers of childbed. Then follows MCCLINTOCK'S description of the "epidemic" of puerperal fever in Dublin in the years 1854–55. This clearly shows an outbreak of puerperal fever, virulent at the commencement, milder towards the close. But such outbreaks do not prove the epidemic character of the disease. Similar outbreaks of pyæmia and septicæmia were by no means unknown in the surgical wards of our hospitals at no very distant period, and no one would for a moment entertain the suggestion that they were epidemics. But it may be said that such outbreaks of pyæmia did not occur in the private practice of the surgeon, while they did in that of the obstetrician; and this is true. Puerperal fever, however, dogged the steps of individual practitioners and nurses, but did not attack indiscriminately all or "large numbers" of women confined in a certain locality. This difference in the private practice of the surgeon and of the obstetrician is easily explained by the difference in the parts injured, and the ease with which they can be cleansed in surgical cases. Outbreaks of pyæmia in hospitals have been traced to causes which are remediable, and not to epidemic influences, although pyæmia and septicæmia are in some degree subject to such influences, and are more prevalent at certain seasons and when other diseases are rife, as was shown by the Committee appointed by the Pathological Society to report on Pyæmia. These facts point to the attendants as the carriers of a poison, and not to a poison generally disseminated through the air.

No one doubts that septicæmia and puerperal fever are transmissible diseases, and the researches of PASTEUR have shown how outbreaks of these diseases are virulent at the beginning and milder later on. In the diseases the virus of which he has isolated and cultivated (chicken cholera, charbon, and hydrophobia), he has found that successive generations of the virus possess feebler infective properties, until finally it entirely loses its character as a virus. The same appears to hold good in the transmission of certain poisons through the human body, and amongst them that of puerperal fever. In face of all the facts about this malady which have as yet become known, it is not possible to regard it as a disease at any time epidemic, and all the evidence tends to show it to be a disease transmissible, and that the agents in its transmission are the attendants on the sick. By acting on this assumption, the results obtained have been far superior to those obtained on the older—epidemic—view of the disease.

No apology is needed for returning to the subject on which we commented last week now that the full text of

Digitized by Google

Dr. KOCH'S address is before us. The predominant interest of the subject, and the necessity that Dr. KOCH'S views should not be misinterpreted, are sufficient reasons for again referring to it. And in the first place be it remarked that, although the interesting observation remains that the bacilli of cholera are less tenacious of life, and are apparently even destroyed, by the bacteria of putrefaction, it would be going too far to take seriously the inference which we somewhat satirically drew from this fact last week. Certainly no sane sanitarian would dream of encouraging putrefaction to get rid of cholera; but what is of importance to know, and what Dr. KOCH himself deduces, is that none of the usual measures taken to arrest putrefaction will destroy the morbific virus of cholera. He thinks that such measures are carried to an extravagant degree (although it might be asked if this were possible in many places we could name), and are yet of no avail in stamping out the disease. We should hardly have raised this point again were it not for the fear lest the real import of this apparent incompatibility of the putrefactive and the pathogenic micro-organism should be misapprehended. The portion of the address of which we publish an abstract to-day deals with many important problems. Some of the strongest criticism—e.g., that by Dr. CAMERON at Belfast—levelled against the conclusion of Dr. KOCH that his microbe is the cause of cholera, has been based on the failure of his attempts to communicate the disease to the lower animals. He fully admits the failure, but he points out that those animals never have cholera spontaneously; and he explains much of their immunity by the fact that the bacilli are destroyed in the stomach and never reach the intestine. Moreover, he urges that the bacillus is a parasite, and most parasites have their special hosts—an argument which may, however, prove too much. The fact that the comma bacillus—which, by the way, seems to have relatively slight tenacity of life—is destroyed by the gastric secretion, suggests that in the human subject much stress must be laid upon digestive derangement in favouring the passage of the bacillus into the bowel; and the well-known fact of the danger of consuming indigestible matters in cholera times is invoked to support this doctrine. In fact, there are few points even in the very wide etiology of cholera which Dr. KOCH does not fail to gather up and to explain on his bacillus doctrine. We may instance especially the evidence of infection by contaminated water, and the equally accepted fact of infection of those who wash the foul linen coming from cholera patients. Here we have facts well established and admitted, which harmonise very well with the view taken by Dr. KOCH, especially as he has found the bacillus in the linen and in befouled water.

He passes in his address from the conditions of individual infection to those which influence the course and progress of epidemics, and he does not hesitate to deal freely with the large questions that have so long and so often been debated by epidemiologists. He is convinced that the bacillus is the cause of cholera, and straightway he proceeds in the clear and comprehensive manner of which he is master to depict the home of the fateful parasite in the Ganges delta, whence it is conveyed, not by the air or in a dried state in merchandise, but by the human body, so that the dangers of the spread of epidemics increase in proportion as facilities for travel and intercourse are multiplied. Nor is there anything new in this conclusion; but hitherto we have had to endure views of an opposing character on this very point. Dr. KOCH may be an enthusiast, and the eminent men he has gained over to his views may also be under a delusion; but, seriously, we confess that more hope of eradication of this scourge is raised by following his leadership, and acting in good faith in the direction that he points, than by accepting any of the theories and speculations of which the world has had so many. For is now hardly a question of theory, but a very plain practical fact, and one upon which it is possible to act in attempting to check the ravages of cholera on the shores of the Ganges and to limit its diffusion abroad.

At the time of writing we learn that the report of MM. STRAUSS and ROUX has been laid before the Paris Academy. It contains statements based on their observations last year in Egypt, and recently at Toulon, which are far more confirmatory of Dr. KOCH'S view than has been generally supposed. Thus they have observed the presence of the comma bacillus in most cases examined, and believe that this organism plays an important part in the disease. Although they hesitate to regard its relation to cholera as a causal one, they nevertheless arrive at the same conclusion as Dr. KOCH, in the belief that if this be so the action of the bacillus must be ascribed to a power possessed by it of producing a poisonous substance—the choleraic virus. At the same time they announce the detection of the comma bacillus in other diseases, but no mention is made of the results of cultures in such cases—a point in diagnosis on which Dr. KOCH lays much stress.

THE term Pharmacology is one by no means easy of definition. To it is no longer assigned the old significance which it bore as a mere synonym of Materia Medica. It is the science of the action of remedies, and deals with the modifications produced in healthy conditions by the operation of substances capable of producing modification. It constitutes the chief basis for the application of remedies in disease, and is an important connecting link between materia medica on the one hand and the art of medicine on the other. The term Therapeutics is familiar enough to the practical physician, and has for its object the treatment of disease. Authors are not agreed as to the limits to be assigned to the subject, for in its most extended sense it embraces all known methods of cure. Of late the combined subjects of Pharmacology and Therapeutics have assumed such importance in our educational course as almost to oust the old-fashioned Materia Medica. That the change is beneficial cannot for a moment be doubted. Materia Medica was always an unpopular subject both with students and teachers, and it is difficult to see what benefit could accrue from learning by rote the botanical names and characters of a number of drugs which were seldom seen, and rarely or never prescribed. A knowledge of Pharmacology or the physiological action of drugs, on the other hand, not only strengthens the intellectual faculties, but goes far to lay the foundation of a good practical knowledge of the treatment of disease. The change which has taken place in the teaching of the so-called Materia Medica is well illustrated by a comparison of the examination papers of to-day and of five years ago. The old-fashioned

Digitized by Google

examiner in Materia Medica required the student to "give a list of the leaves in the Pharmacopœia," or asked him to enumerate the roots named in that publication, "with their differential characters." Such knowledge was "crammed up" slowly and laboriously, and was of not the slightest value when attained. The questions now asked, at all events at all the better-class examinations, are of an entirely different stamp. Here, for example, is one taken at random from the calendar of the University of Edinburgh:—"Give an account of the physiological action of atropia both on man and the lower animals. Mention some of the alkaloids to which it is most closely allied, and some to which it is antagonistic. What substances applied typically dilate the pupil, and what contract it?" Questions such as these not only test the student's reading, but ensure the possession of a certain amount of knowledge, which cannot fail to be of the greatest value to him in his future career.

If further proofs were needed of the enormous strides made of late in this department of science, they might be found in the institution by the British Medical Association of a new section of Pharmacology and Therapeutics. It seems to be generally admitted that this section was the event of the meeting at Belfast. It was at one time thought that Pharmacology would never be popular with the great bulk of the profession, but that such is not the case is shown by the fact that this special section was crowded during the whole meeting, even when other departments languished and were poorly attended. It must be admitted that the promoters of the section of Pharmacology took a somewhat liberal view of the subjects included within its scope. Thus we find a debate on the British Pharmacopœia and the Patent Medicines Stamp Act culminating in the passing of several very practical resolutions; a discussion on antipyretics and the therapeutic uses of the oleates; a series of demonstrations on the action of various remedies on the frog's heart, and of instruments used in tapping the chest; and other features of equal interest. This may have been carrying matters rather far, but it must be admitted that if it were a fault, it was a fault on the right side. We do not see that the question of the repeal of the Patent Medicines Stamp Act could have been discussed equally well in any other section, and the absolute necessity for bringing the matter prominently before the profession cannot for one moment be doubted.

At the meetings of the British Pharmaceutical Conference matters relating to pharmacology and therapeutics are often discussed incidentally, although necessarily the bulk of the work is devoted to pharmacy. The presidential address is always looked forward to with considerable interest; and that delivered by Mr. JOHN WILLIAMS at Hastings on Tuesday last was evidently listened to with especial pleasure. During the last two years we have had occasion more than once to comment favourably on the orations published by Professor ATTFIELD in his presidential capacity. The year-book issued by the Conference contains an authentic record of the progress of pharmacy during the preceding twelve months, and is of considerable use to original workers.

The part taken by THE LANCET in the promotion of the science of Pharmacology will not be forgotten. From time to time special articles on the subject appear in our pages, a course which has doubtless stimulated the British Medical Association to take the step above referred to; and there is hardly an original paper, either on the physiological action of drugs or their practical application to the treatment of disease, which has not received attention at our hands. Pharmacology has undoubtedly a brilliant future before it, and great credit is due to those who have devoted their time and energies to promoting and popularising the subject.

WHEN the three Goddesses met on the summit of Mount Ida, the envy, hatred, malice, and all uncharitableness with which each regarded the other two, as possible possessors of the apple about to be awarded by the too happy shepherd, were no doubt veiled under the usual compliments about personal appearance of which the sex is so great a mistress. But had these ladies had an idea of the prophetical significance of the scene which they were unconsciously enacting, especially of the apple, and of the ten thousand miseries which it would bring upon the inhabitants of the world in the end of the nineteenth century, charity forbids us to doubt that they would have resorted to the quickest and most certain means for its destruction. Whether they would have thrown it at the head of PARIS or down the slope of Mount Ida, or whether they would have divided it into three segments and then and there solemnly masticated it, or given a quarter or the whole to PARIS, we have not time now to speculate. But ZEUS or HERMES would have won our eternal gratitude had he whispered in the ear of any one of the three that the apple was an ovarian tumour, and that the three Goddesses were the prophetical types of the general surgeon, abdominal surgeon, and obstetrician respectively. The original subject has been often painted, but we recommend the antitype to the Royal Academy, and do not doubt that they will find willing sitters for each of the three characters.

We need not further allude to the constant discussion and wrangling on the subject which is heard at our Societies and is to be read in our periodicals, except to remark that the substance of the apple is unmistakably golden, and that the chink of fees seems to us to have repeatedly and effectually drowned the feeble voice of the patient, whose interests have surely *some* claim on our attention. Since ovariotomy became a thoroughly established procedure, it has been practised under various conditions at different hospitals. At some the obstetric physician under whose care the case probably comes in the first instance retains it; but the general tendency has been for the surgeons to take the operation away from the obstetric physician, and either for the surgeon to operate on each case he gets, or for a surgeon to be appointed to perform all ovariotomies for a term of years. Another plan (if plan it can be called) is for all the surgeons and the obstetric physician to operate whenever they can. In discussing the question, a glance at the history of the operation will show that it owes its advances to surgeons—that is, to those who have made a special study of abdominal surgery; and that they find life too brief, and a day of twenty-four hours too short, for the study and practice of their subject. The claim of perfecting the operation rests, then, with the abdominal surgeons, and it is plain that its pursuit involves a vast expenditure of time and study.

In calculating the relative success of various operators, we

Digitized by Google

are met by the first of the Hippocratic aphorisms, "Experience is fallacious," which might be extended to the statistics of abdominal surgery until, at least, such time as the whole truth on this head shall be authoritatively published by the special and other hospitals, including the relative results of those who adopt or reject antiseptic measures. In a matter so serious as abdominal surgery, it is surely not too much to ask that operators shall combine in a search after the truth, with a little less apprehension on the score of their individual advancement. Still, laying this question aside, it seems abundantly proved meanwhile that large experience conduces in a marked manner to success, and that percentages derived from small numbers need not be considered. A man who has operated once must either have a success or a mortality of 100 per cent.; while a man who has operated once less often may say that he has never lost a patient after the operation. We should therefore lay down the principle that it is for the advantage of the patient that operations should be to some extent centralised. In the metropolis we imagine that this is what actually happens—in private at least,—and that patients require to be assured as to the number of operations successfully performed by the proposed operator before entrusting themselves to his hands. In the provinces the circumstances are different, and need not here be discussed.

But perhaps the most burning question is that of the allotment of abdominal surgery at the general hospitals, and we have already referred to its various solutions. At the commencement, we feel bound to repeat what we stated above, that the question has, on the whole, been fought in a thoroughly selfish spirit on both sides, and that the solution most generally adopted has usually been arrived at by the very simple process of outvoting, which is not difficult, seeing that there are perhaps four or more surgical votes to one obstetrical vote, taking the average composition of the staffs of the London hospitals, the physicians practically remaining neutral. Of all possible states, the worst is probably that arrived at by a process not so much of solution as of dissolution or disintegration on the great principle of "grab"—"that those should take who have the power, and those should keep who can," surgeons and obstetricians agreeing (or disagreeing) to scramble for cases.

What, then, it may be asked, are the principles which should guide us to a conclusion when the subject is debated? First, that general hospitals should be or become capable of undertaking and teaching any department of practice without resort to special hospitals. Secondly, that to attain satisfactory results concentration of material is absolutely necessary. This means that at each medical school some one person should be appointed to perform ovariotomies for a term of years. The question whether the ovariotomist should be one of the surgeons or the obstetric physician, although practically the NEBUCHADNEZZAR'S furnace of the whole controversy to the parties concerned, seems to us a matter of far less importance. There are attached to some hospitals obstetric physicians who are also thoroughly skilful and competent surgeons, while at other hospitals the same cannot be said. The subject can conveniently be approached from either side. To the obstetric physician pelvic anatomy and the growth of pelvic tumours are (or should be) more familiar than to the surgeon; to the surgeon the treatment of wounds is naturally more familiar than to the obstetric physician; both have advantages and both have disadvantages, but neither is competent to deal with abdominal surgery until such time as he shall have studied abdominal surgery. We confess that against the entrance of any person not specially skilled and experienced we should feel disposed to keep our own peritoneal cavity and those of our friends peremptorily closed. We do not believe that success is to be reached in any other way than that which we have indicated, and the opportunity of undertaking an occasional case will do the operator more further good than to enable him to answer in the affirmative the question of a possible patient or her adviser: "Have you ever done the operation?" The question should be discussed on far higher grounds.

With regard to the detail—how the question is to be decided (if raised) at any medical school—we should suggest that it would be better and fairer not to settle the matter in full conclave, on account of the necessary disparity of votes, but to refer it to an impartial and disinterested subcommittee, who should hear both sides and decide accordingly; and we would conclude with the opinion that these little domestic matters are best settled at home.

IN an article on *Primary Education in Scotland*, in *The Times* of the 6th inst., a very remarkable fact is stated: that "not only has no sound of the cry of overpressure been heard from across the Tweed, but, as a fact, nothing has been done outside the sewing schedule to provide against the practice and the ill effects of overpressure." Considering the outcry which has been raised in England on this subject, it appears important to ascertain in what respects the school system of the two countries differs in its working, and if such difference may account for this remarkable fact. The results obtained as the outcome of the system negative the supposition of a difference in the amount of work exacted from the children. "Standard by standard, Scotland scores above England without a single exception; and in the summary of results, Scotland passed 92·59 per cent. in reading (England 89·14), 90·28 per cent. in writing (England 82·03), and 85·99 per cent. in arithmetic (England 77·51), making a general percentage of 89·6, against 82·9 in England." Not only in the three "R's" did Scotland take the lead, but in the specific subjects. "In England under 10 per cent. of the separate departments examined under the new code took up these subjects, and the number of children examined in them was 2¼ per cent. of all the children in average attendance in all the schools inspected during that period. But in Scotland 55 per cent. of all the several departments presented scholars for examination in specific subjects, and the number of children so presented was 14 per cent. of all in average attendance." These statistical facts appear to show clearly that the difference in the results upon health has not been gained at the expense of the knowledge to be acquired through the medium of the school. There is a point to which we have not yet adverted which may not improbably have a marked influence upon the question of overpressure, and that is the difference in the ages of the scholars in the two divisions of the kingdom. In England 9·74 per cent. of the number on the books were under five years of age, while in Scotland the

Digitized by Google

proportion was only 2·2 per cent.; or, calculating the proportion on the numbers living between the ages of two and five years, twenty are at school in England and only four in Scotland. This difference seems to call for a careful inquiry into the ages of the children who are alleged to suffer from over-pressure. If it should prove to be among the younger children, it is obvious that some change is required in the amount of teaching, or the mode in which instruction is imparted at the earlier ages. Another very important point for inquiry is into the amount of confinement in the schoolrooms (seldom sufficiently ventilated) to which these younger ones are subjected. It is in them that the evils of crowding and of a long continuance of breathing a vitiated atmosphere may be expected to be most fully and most quickly developed. A careful compilation of accurate numerical facts, a comparison of those only which are strictly comparable, and a separation of the data relating to large towns, small towns, and rural districts, are all requisite to ensure accurate deductions on this important question. We trust the subject may be taken up by some competent person who has access to the documents necessary for such an inquiry, and whose object is to arrive at the truth, without any regard to upholding existing systems or substituting for them impracticable crotchets.

THE sense of almost absolute hopelessness which one feels as regards the cause of medical reform is not mitigated by the account of the discussion of the subject at the late meeting of the British Medical Association. The principal speakers were Dr. WATERS, Dr. CAMERON, M.P., Dr. JACOB, Dr. B. O'CONNOR, Dr. GRIMSHAW, Professor STOKES, and Mr. HART. Dr. WATERS, in the absence of any recent triumphs of the Association in the arena of medical reform, recounted the victories implied in the Act of 1858. It is time to stop all boasting of this kind in the sense of shame and disappointment at the present impotence of either the profession or the Association to procure legislation having for its object the amendment of that very imperfect piece of Parliamentary work. This Act put the interests of medical education into the hands of a body from which the representatives of the profession itself are excluded, and in which the representatives of medical corporations which have their pecuniary interests in low examinations are powerful, if not predominant. We admit cheerfully the untiring and self-denying labours of Dr. WATERS, and see with regret the manifestation of a disposition to disparage and supplant him. But he and his colleagues are not without blame. He and the Reform Committee are a little too self-complacent in regard to past achievements, and have shown too great a readiness to concede everything, and take anything that is called a Medical Bill, however mutilated or eviscerated. At the meeting at Belfast last week, it was practically admitted that the Reform Committee have been unfaithful to the fundamental principle of medical reform—a one-portal examination—in which the representatives of all the medical authorities should be represented. It was also stated that the Committee in the recent session came to the conclusion that it was for the *Government* to consider the amendments of Sir LYON PLAYFAIR, which amendments the Committee determined not to oppose. When did the Association so lose its sense of power? When did it discover that it was no part of its duty to oppose even the Government yielding to the pressure of Sir LYON PLAYFAIR on a fundamental matter? There have been times when the Association had opinions of its own, and when it had the courage of its opinions; when it dared to say, or to join others in saying, that it would be no party to a mutilated Bill. In 1870 it refused a Bill without the principle of direct representation as we ourselves did; and now we find it conceded on all hands. But if anyone had said in 1870 that Dr. WATERS and his colleagues would live to accept a Bill from the Government without the principle of a one-portal or conjoint board, he would have been judged to speak in ignorance of men and of the great principles involved. But this is what things have come to. The Reform Committee—not with its recent ominous infusion of new blood, but under its old constitution—came to the humbling conclusion that "it was for the Government" to consider amendments fatal to the fundamental views of the Committee and the profession, and "the Committee did not oppose them"! Never was there a more humiliating surrender on the part of men once powerfully representing a great Association. We cannot call it a mere surrender; we must characterise their conduct as in the highest degree unfaithful to their own record and to the commission which they had received from the Association. We think Dr. WATERS will agree with us that he had no authority from the Association to accept a Bill without the principle of a conjoint board, and that when he and his colleagues agreed to do so, or to connive at the Government doing so, they were acting on their individual judgments and betraying a vital principle they were appointed to support—a principle asserted by the Medical Council and by the Royal Commission, and accepted in every Government Bill for the amendment of the very imperfect Act of 1858.

We leave these gentlemen to their own reflections, and wish them joy of their new colleagues in the Committee, one of whom, Dr. B. O'CONNOR, with a modesty that cannot be too much admired, contrives to imply that if "fifty or sixty" amendments had been accepted the Bill might now have been law. Dr. JACOB really has many of the instincts of a medical reformer; but from some cause or other he is "sore let and hindered." We do not do him the injustice to believe that he would approve the amendments which bristled on the notice paper, and which, as a reasonable Irishman, he must see were meant to produce the miscarriage of the Bill. But for some reason or other, whenever a medical bill is on the eve of success, Dr. JACOB curiously finds many points of sympathy with its enemies, and when the hare is in sore need of friends he comes in in full cry with the hounds. Dr. JACOB wants reform, but it must "not necessarily disturb existing licensing institutions." It is impossible to get medical reform without disturbing existing licensing institutions, and a reformer who is so connected with institutions as to make this condition had better leave reform work to others.

It is far better to admit the utter hopelessness of the cause of medical reform, and to leave students to be fleeced and worried and tempted by rival diploma "shops"—to use Sir DOMINIC CORRIGAN'S expression,—than to expect reform from such quarters. It is far better to see that, in the present state of Parliamentary procedure and parties, medical

Digitized by Google

institutions in England are entirely at the mercy of Scotland and Ireland, and to hope for better times. At least, we shall be no parties to reforms so delusive and so unfaithful to the profession and to the public, and we do not doubt that we express the feelings of the profession and even of the Association.

Annotations.

"Ne quid nimis."

DR. KLEIN ON THE CHOLERA BACILLUS.

THE following passage in his papers on Micro-organisms and Disease, now appearing in the *Practitioner*, indicates the opinion which Dr. Klein at present holds respecting the comma bacillus; and it will be interesting to observe whether the extended personal research he is about to undertake in India will serve to alter the somewhat sceptical attitude he here maintains respecting Koch's discovery. Dr. Klein says:—"In the reports from India by Dr. Koch, as the head of the German Commission sent to investigate the recent outbreak of cholera in Egypt, we notice that, like the French Commission, they failed to communicate the disease to animals; that the German Commission failed to discover any specific organism in the blood of patients suffering from cholera; that the intestines contained in their cavity and walls numerous peculiar 'comma-shaped' bacilli, which Koch considers to have a special relation to the disease. Considering the state of the intestine in this disease, the presence of the bacilli, however peculiar, in its walls is in itself not convincing proof of their specific nature. Considering, also, that animals are as yet found insusceptible to cholera, artificial cultivations of the bacilli, successfully accomplished by Koch, cannot be tested. From the artificial cultivations of these comma-shaped bacilli Koch learned that it is necessary that the nourishing medium should have an alkaline reaction, and that the bacilli are easily killed by drying. Koch found these comma-shaped bacilli in linen soiled by the cholera dejecta, also in the water of a tank that had produced cholera in several people who had partaken of it. As soon as the bacilli disappeared in this water cholera cases ceased. My friend Mr. A. Lingard has placed at my disposal sections through the human intestine from cases of dysentery; there are seen in the superficial parts of the necrosed mucous membrane large numbers of putrefactive bacilli. In some cases, however, in the depth of the tissue there are found, amongst the extravasated blood-corpuscles, numbers of very fine, long, straight, or, more commonly, curved bacilli and bacillus filaments; some are distinctly made up of a chain of long bacilli. They stain well and conspicuously in methyl blue."

THE REPEAL OF THE PATENT MEDICINES STAMP ACT.

THE question of the repeal of this obnoxious tax continues to excite considerable attention both in and out of Parliament. In *The Times* of the 7th inst. there appears a remarkably able letter, signed "A Member of the Royal College of Physicians," in which the facts of the case are set forth very clearly. The matter is one of such far-reaching importance, that its ventilation in the public press is not only expedient, but necessary. "Is it conceivable," says the writer in question, "that the Act of 1812 was ever contemplated to lay an embargo upon some nine-tenths of all pharmaceutical preparations? Could any rational man suppose that it was to range side by side a 'convulsion oil' and sulphate of cinchonidine or quinine wine? Anyone at all conversant with the history of medicine and therapeutics, or the science which presides over the rational study of the physiological action of drugs, must be aware that in 1812 empiricism was the queen-mother of the healing art, and made her fiat supreme; while therapeutics as a science was yet to be born, pharmacy was of the rudest description, and was restricted within the narrowest domain. Such considerations, one would have thought, might have tempered the zeal of Somerset House with a spice of common sense." Appended to the Act is a schedule, in which are included some five or six hundred quack salves and catch-penny panaceas, most of which have fortunately long since passed into the realms of oblivion; but intermingled with quack "cooling opening pills" and bogus "pectoral lozenges," there appear the words "foreign medicines of all kinds, except drugs." To the uninitiated this clause may appear harmless enough, but its full force will be realised when it is considered that many of our most valued preparations are manufactured abroad, and can only there be made, as it is essential that they should be concocted from foreign plants, and while these are yet fresh. Referring to the responsibility incurred by any Government which permits the unrestricted sale of deadly poisons under the guise of "patent medicines," it is pointed out that no measure short of the total repeal of the Act will prove of the slightest avail. Dr. Balthazar Foster, in a letter to *The Times* of Wednesday last, speaks of it as a law not only indefensible as a matter of commercial policy, but decidedly injurious to the public health. Passed originally as a means of raising revenue for the war against Napoleon, it has survived till the present day, in direct contravention of our policy of free trade, till now, under its most recent interpretation, it threatens to cripple commercial enterprise and obstruct scientific inquiry. Its baleful effects in giving a *quasi*-Government sanction to many worthless preparations, and thus bolstering up a nefarious traffic, cannot be too strongly condemned, more especially as the poor and the ignorant are the chief sufferers." It is a source of satisfaction that the subject has been so warmly taken up not only by the "Member of the Royal College of Physicians," but by the London and provincial press generally, many of the leading journals devoting long articles to the subject, and all, without exception, advocating the adoption of prompt and energetic measures. In *The Times* it is pointed out that, if a medicine be good, it is assuredly unjust to raise its price by a tax; while, if it be deleterious, or if it does not possess the properties which its makers claim for it, it is wrong that it should bear a Government label which may mislead the buyer. "In its origin, doubtless the Act was partly intended to stop the traffic in cheap unlicensed drugs which once could be hawked in the streets, but it has long outgrown its uses in this respect." The attention of the House of Commons, as our readers are aware, was drawn to the subject by a series of pertinent questions by Mr. T. P. O'Connor, who asked the Chancellor of the Exchequer if his attention had been called to recent articles in THE LANCET advocating the repeal of the Act; if he had any information to confirm the statement that the Act, instead of discouraging, stimulated largely the sale of quack medicines; and whether he was aware that the large number of deaths that occurred annually in children was on good authority attributed to the administration of poisons in the shape of secret medicines. Mr. Childers, in reply, practically admitted the truth of the statements implied in the questions, and undertook to obtain from the Board of Inland Revenue a report on the subject, which he promised to study carefully. He added that he could hold out no hope of repealing a tax which brought in £160,000 a year. This answer must, of course, be considered as being merely tentative, and we are convinced that when the Chancellor of the Exchequer is fully informed of the circumstances of the case, he will at once see that the repeal of the Act is

Digitized by Google

imperatively demanded. No Government can afford to maintain a tax which doubles and trebles our infant mortality. It is perhaps not generally known that soothing syrups and other noxious preparations containing opium are responsible for over 40 per cent. of all deaths from poisoning in England, whilst in no other European country does the death-rate from this cause exceed 1 per cent. We are glad to find that notice has already been given by the member for Galway of his intention to introduce, at the earliest possible moment, a Bill for the repeal of the Act. Its retention would be not only a disgrace but a national misfortune.

PREVENTION OF HYDROPHOBIA.

FRENCH science may indeed claim a new title to the gratitude of humanity. Whilst granting this, we do not wish to rush to the hasty conclusion that hydrophobia is to be banished from our midst; only, if we can believe our eyes and ears, it seems that we are within measurable distance of this glad state. What has Pasteur done? He has—if our information be accurate, and we have no reason to doubt it—done something to twenty-three dogs, thereby rendering them, at any rate for a time, incapable of suffering from rabies. Side by side with the free animals he has placed others which may be regarded as servile to the yoke of hydrophobia. Of the latter series, six were bitten by mad dogs, three of them becoming mad; eight were subjected to intravenous inoculation, all becoming mad; and five to inoculation by trepanning, all likewise becoming mad. On this showing, sixteen out of nineteen dogs died when a dose of the virus of rabies was sewn in them; whereas, of twenty-three protected dogs, none succumbed, although the virus was brought in the most effectual manner into the tissues of each animal. It is a well-known fact that many more persons are bitten by rabid animals than suffer from hydrophobia. What the exact proportion may be is not satisfactorily known, but in dogs it would appear that about half the number bitten become rabid. There are two explanations of the escape. The first is expressed by saying that no virus gets into the tissues of the body. The second suggestion, though possible, is less plain. It is to the effect that some organisms are unsuitable for the development of the rabid poison. There is analogy for this contention. Some individuals are believed to be insusceptible to the poison of scarlet fever, and this statement also applies to other acute specific diseases. The questioner of nature may ask how these facts are to be explained? And although we are on very unsafe ground, still science does afford some clue to a possible explanation. If we remember rightly, Sir James Paget has asserted his belief that a severe attack of typhoid fever may do away with the protection afforded by a previous attack of small-pox. Typhoid fever so modifies the constitution that the protoplasmic organism once again becomes favourable to the growth and development of the germs of small-pox. Inoculation with the attenuated virus of hydrophobia gives a dog immunity from the disease, just as similar treatment preserves a sheep from charbon; in other words, the physical basis of the canine organism is so altered that it no longer affords nourishment for the evolution of the poison of rabies. We cannot help giving expression to another idea in this connexion. A modification of the constitution may be effected by other means than inoculation with thinned virus. Is it not possible that some of those bitten by mad dogs do not become hydrophobic because they belong to a particular diathesis, the material basis of which is not favourable to the development of the germs of rabies? Supposing, for the moment, that individuals of the gouty type were insusceptible of hydrophobia: we might easily understand how external circumstances would be able to modify the physical basis of the organism; how, in short, the soil might be transformed so as no longer to afford nourishment for a particular plant. But these are pure speculations, and not the kind of wares which the practical physician would care to deal in. The announcement that the Commission charged by the French Government to investigate the assertions of M. Pasteur has fully confirmed the discoveries of the great chemist is at present the object which commands our attention. The Committee proposes hereafter to make further experiments as to the duration of the immunity afforded after preventive inoculation; and, further, it proposes to investigate the point whether inoculation with attenuated virus will save an animal already bitten by a mad dog. A word of scientific caution before we finish. It is imperative on Englishmen to institute an experimental inquiry on hydrophobia, not only for the sake of the honour of their country, but also for the sake of truth and science. No fact of importance can be too firmly established, and no truth can be too highly burnished.

PIGMENTATION OF BRAIN.

ALTERATIONS of colour are amongst the most striking changes which the pathologist encounters. It has now for some time been held that all pigmentations, whether physiological or otherwise, own the same physical origin—viz., hæmoglobin. Although the end and the beginning of the materials concerned in the process of pigmentation may thus be said to be known, there nevertheless remains for investigation the whole field of intermediate changes. M. Baillarger has recently published several cases of slate-coloured alteration of the brain, and has endeavoured to determine the relationship of this lesion with the sacral eschars so often observed in the paralysed insane. The discolouration, more or less marked, was found to be accurately limited to the grey matter of the cerebral cortex. The most frequent sites of the change were the base and posterior parts of the cerebrum, though it was also seen on the upper surface of the cerebral hemispheres, and was always well marked about the Sylvian fissures. The arachnoid and pia mater sometimes showed no other alteration than that usually met with in cases of general paralysis, but more often a greyish purulent infiltration was detected. The slate-coloured change was not discovered in cases of paralytic dementia only, though it was more commonly seen in this disease than any other. The cerebro-spinal lesions which may come on after sacral sloughing belong to three classes. These sacral diseases may set up the slate-coloured pigmentation with purulent meningitis, or either of the alterations alone. The author asserts that the *coloration ardoisée* of a part of the cerebral convolutions is evidence of sacral sores in the absence of cranial lesions and purulent otitis.

THE PHYSICAL TRAINING OF GIRLS.

MR. NOBLE SMITH'S lecture, delivered a fortnight ago at the Health Exhibition, on "Postures in School," touched a vital point in our social management. The lecturer dealt with some of the errors of attitude and exercise which prevail in the recognised training of girls at school, and which have been found to interfere most seriously with their physical development. After adverting to the slowness of ossification in the long bones and vertebræ, in condemnation of the practice of forced walking or sitting up, so commonly adopted with infants of either sex, he proceeded to make the general statement that freedom, not restraint, of posture must rule the carriage of growing girls, especially at school. With boys there is no need for such a rule. Designed for active life, the liberty of their joints and muscles is allowed them. For girls, on the contrary, though action enters largely into healthy womanhood, antique pre-physiological

Digitized by Google

decorum has provided many needless restrictions. In class hours they must sit erect with unsupported backs, and afterwards endure the monotony of piano practice in the same constrained position. The play-hour brings no sufficient change, but is passed in sedentary quiet or in regimental marching. All this implies too little variation of movement to secure the benefit of exercise, and a too conventional dread of ease to allow that task-work should generally become a prompt or willing service. Mr. Noble Smith very fairly demands a change in this stilted arrangement. He asks that suitable backs should be attached to all school seats, that desks should be so contrived as to height and slope that they may be leant upon and become a means of relieving spinal tension without producing a chest-contracting stoop, that the light for equally good reasons should fall from left to right, and particularly that the period of piano practice should be strictly moderated. In regard to muscular recreation for girls, we have long maintained that almost unlimited variety as to method may safely be conceded to them, and this opinion is plainly expressed in the lecture under discussion. Lawn tennis, gymnastics, swimming (an art too little favoured by men as well as women), and cricket even, all come in for a share of commendation. Let us add but one caution to this part of an admirable paper—namely, that while there is little need of restriction as to the kind of athletic play, there is real occasion for its limitation as to time and degree. The healthy growth of both sexes depends upon the same conditions supplied to each in its own measure.

DECUSSATION OF NERVES.

PERHAPS in the majority of individuals the pyramidal tracts decussate at their well-known site in such a manner that the bulk of the fibres of one side passes over to the opposite lateral column of the spinal cord, whilst the small remainder continues downwards in the anterior column. This arrangement is, however, subject to considerable variation, and nothing can be positively asserted until a systematic investigation has been made, which is practically impossible in man. Nevertheless, the knowledge which is expressed in the preceding sentences may be regarded as legitimate inferences from a study of diseases of the brain. From careful clinical observation, it seems not at all improbable that further complexity ought to be introduced into the anatomy of the nerve-paths in the brain. Secondary degenerations of cerebral origin are sometimes exclusively confined to the opposite lateral column of the cord; sometimes to the opposite lateral column and the internal part of the anterior column of the same side as the cerebral lesion. Pitrès has also collected ten cases of unilateral cerebral lesion, in which the secondary degeneration occupied both lateral columns of the spinal cord. The cerebral disease varied in its nature, extent, and site; the secondary sclerosis traversed the peduncles, pons, and anterior pyramid, and then abruptly became bilateral below the decussation of the pyramids. The secondary changes were sometimes exactly symmetrical, sometimes more marked on the same side. The columns of Türck were generally spared, or presented but slight damage, whilst the other structures of the cord were normal. M. Pitrès has sought to explain the coexistence of symmetrical medullary lesions with unilateral disease of the brain. His explanation is founded on the individual variations of the decussation of the pyramids as described by Türck and Fleming. There may be simply a crossed pyramidal tract, or there may be a direct as well as a crossed pyramidal tract, and each may bear almost any numerical relation one to the other. Further, the pyramidal tracts of the two sides of the brain may or may not proceed after the same plan; the decussation may be complete for one tract and incomplete for the other. In certain subjects it seems possible that the fibres of one pyramidal tract in the bulb may split into two portions, one of which may proceed down the opposite lateral column, whilst the other descends in the lateral column of the same side. The disturbance of balance and progression appears to be more persistent and more grave when the secondary sclerosis is bilateral than when it is unilateral. Partial paraplegia, exaggeration of the knee-jerk, and contracture of the lower limbs may exist, however, where the sclerosis is unilateral.

METROPOLITAN ASYLUMS AND THE HOUSING OF THE POOR.

THE Royal Commissioners on the Housing of the Poor have apparently found reason to appreciate the difficulty pointed out by Mr. George Sims some months ago as to where the very poor shall live while the slums are being demolished, and the dwellings intended to replace them are as yet unbuilt. Mr. Torrens's proposal, that the prisons and lunatic asylums of the metropolis should be removed into the country and their present acreage devoted to the use of the Commissioners, is a plan worthy of consideration. The question of expense is one with which the Commissioners are probably more conversant than anyone else. It is here, if anywhere, that objection is likely to be found. The advantage to the poor which would arise from such a plan is obvious. Building would then proceed unchecked by the difficulty we have referred to, and the transplanted population would gain in health by breathing the air of neighbourhoods which always were more pure than those from which they came. These latter could then be cleared, purified, and built on at leisure. The inmates of the removed institutions would profit in an equal or greater degree by the change from town to country; they would be comparatively out of range of prevalent epidemics, while their safe keeping would be the more assured by their detachment from the Alsatias of crime and poverty which surrounded them in the city. In so far the proposal is a good one, but various considerations of practical convenience must be taken into account when it is discussed, and the question we anticipate will have to be decided on other grounds besides those of philanthropy or sanitary advantage.

HINTS AS TO SUNSTROKE.

A DAILY temperature of from 80° to 90° in the shade, such as we have somewhat uneasily enjoyed during the last three weeks, has not failed to leave its mark for evil as well as good on living objects exposed to it. Fortunately, vegetation gains more than it loses by a continuance of dry and warm weather. It is not so with all of the human population. Already, by ones and twos, the year's total of deaths from sunstroke is mounting up, and preventive measures, little needed in an ordinary summer, have become imperative under the present tropical conditions. A month ago we referred to the risks incurred by children and certain older persons whose heads were often carelessly exposed to the sun's glare without any adequate covering. The need of care which then existed has since much increased. Field-workers and holiday-makers have multiplied tenfold, and with one and all the weather, and how to meet it, is the first consideration. The causes of sunstroke are several. Thus, while we trace the continuity of cause and effect best after direct exposure to the solar rays, we cannot ignore the fact that mere excessive summer heat, intensified and aided by confinement in small or imperfectly ventilated spaces, is equally effectual to the same end. Various circumstances predispose to insolation. Prominent among these is the common and generally senseless habit of using

Digitized by Google

stimulants to quench thirst. The loss of the body by heat is chiefly water. The rational object of drinking in summer is therefore simply to make good this loss with as little stimulation of tissue as may be. Such stimulation tends to raise temperature by needlessly provoking chemical change, and is therefore manifestly prejudicial. He who would enjoy fresh air and sunshine without fear of injury should dress, eat, and drink as lightly as possible. Summer clothing should be, and usually is, light at least in texture. The head and back of the neck, in particular, require to be suitably covered. Many conveniences exist for this purpose. The tropical custom of wearing a damp handkerchief within the hat is occasionally useful. There should be no tight clothing, such as belts or stays, to impede the respiratory movements. All such impediment, by slowing the circulation, provides a condition favourable to heat-stroke. For the same reason excessive exercise or work is dangerous, through the exhaustion which follows it. Alterations in dress devised on these lines have wisely been adopted for the employés on the Metropolitan Railway. It would be well if some similar deviations in uniform were introduced, as far as practicable, by other companies, and in the Government services. Among other preventive measures, cold bathing in moderation must not be forgotten; for prevention, indeed, it is even more valuable than in the event of actual sunstroke, for which it forms a chief therapeutic agent. It is requisite, however, that before immersion the body should not be overheated by prolonged exertion or other cause.

INTEMPERATE MONEY-MAKING BY TEMPERANCE DRINKS.

A VERY sensible letter appeared in the *Echo* of Aug. 11th, in which the writer complained of the extortionate charge which is almost universally demanded for the sale of temperance drinks. No doubt it is fair that demand should stimulate and remunerate supply, but there is a limit to cost beyond which all relation between it and value of material is lost. It must have struck many a one before now that lemonade and ginger-beer at fourpence or sixpence per glass implies a profit to the seller which is simply dishonest in its excess. Probably the cost of manufacture does not amount to one-fifth of this. There does not yet exist any legal restrictions on the sale of such beverages, and, if possible, it were better to meet the evil of overcharge by common agreement on a scale of reasonable prices without recourse to any system of licence. As a mere necessity of public health, it is to be hoped that a branch of industry which has hitherto enjoyed the countenance of all classes because of the justice and reason of its procedure, shall not be suffered to incur damage from the indiscretion of those who live by it.

DETECTION OF BRUCINE AND STRYCHNINE.

THE following tests for these substances are proposed by Dr. O. Lindt (*Pharmaceutical Journal*). For brucine a convenient test is selenic acid containing nitric acid (five drops of selenic acid, of sp. gr. 1·4, and one to two drops of nitric acid, of sp. gr. 1·2). If the fatty oil is first removed from sections of Strychnos nux vomica and S. ignatii by petroleum ether and this reagent used, the laminated cell-walls quickly take on a bright red colour, which gradually turns to orange and yellow, while the cell cavity and the granular substance contained in it remain uncoloured, indicating the absence of brucine. Nitric acid alone does not answer, the colouration of the alkaloid being marked by the formation of xantho-proteic acid. For the detection of strychnine Lindt discards the potassium bichromate reaction, because the violet colour is developed only in immediate contact with the crystal; and the solution of strychnine in sulphuric acid escapes so rapidly from the preparation that no conclusion can be drawn from a subsequent straining as to the original position of the alkaloid in the nux vomica seed. But it is readily shown by a solution of ceroxide sulphate in sulphuric acid, if the fatty oil, grape sugar and brucine have first been removed by maceration in petroleum ether and absolute alcohol. The reagent imparts a violet-blue colour to all the thickening layers of the cell-walls. But the colour quickly disappears, while the deposits of albumen assume a bluish opalescent tint, which finally turns to a reddish-violet. The interior of the cell becomes of an intense red colour. The reagent retains its activity for a considerable time. The microscope is, of course, necessary to follow all the details of these micro-chemical tests.

THE REMUNERATION OF A MEDICAL OFFICER OF HEALTH.

WE are sorry to see that an attempt is being made by some members of the rural sanitary authority of the Chesterfield Union to reduce the salary of Dr. Angus Mackintosh, their medical officer of health, and, so far as we can learn, the only plea which can be alleged for this step is that Dr. Mackintosh has so successfully devoted himself to his official duties, that it is just possible the work of supervising the health of the increasing population in this important sanitary district may in the future not be attended with quite so much labour as heretofore. Whether their contention be a correct one or not, we can hardly imagine circumstances more calculated to repress the energy and zeal which are so much needed in order to secure sanitary improvements, and we hope, both for their own sakes and in the interests of fair play, that the sanitary authority will not adhere to the decision at which they have arrived. The Local Government Board have so far objected to the reduction, and this to a large extent, on the grounds that Dr. Mackintosh has served his district well. It is to be hoped that this objection will be maintained, for if it is, the single vote by which a majority in favour of the reduction has been secured will probably disappear, and a majority holding opposite views may be obtained. The remuneration in this district is by no means high, and the services which have been rendered in it leave nothing to be desired.

A TOO HASTY DIAGNOSIS.

ON August 7th, at the Hants Assizes, before the Lord Chief Justice, an action was tried of the greatest importance to the medical profession. It appears that the plaintiff, Mr. Yarndley, whilst on yeomanry duty in June last became saddle-sore, a circumstance by no means uncommon to persons not in the habit of riding much. In order to protect the abraded skin he applied a handkerchief to the part. On his return home, his wife, not being satisfied in her mind as to the origin of the blood-stains, took the kerchief to a local practitioner (Dr. Pike), who pronounced in favour of the husband's misconduct. Nor did he retract his expressed opinion after he had personally examined the plaintiff at the invitation of the latter. Horrified at the charge made against him, Mr. Yarndley sought the advice of several doctors in the neighbourhood, who unanimously declared that the diagnosis made by Dr. Pike was incorrect, and, with true professional courtesy, advised him to withdraw it. For some reason or other Dr. Pike failed to do this; hence the action brought by the plaintiff to clear his character from the aspersions cast upon it. Apart from the fact that no manner of stain upon clothing could in itself be taken as proof of venereal disease, the circumstances were strongly suggestive of what was no doubt the real explanation, for the wound on the

Digitized by Google

thigh exactly corresponded with the blood-marks on the trousers. We do not for one moment suppose that the defendant acted from vindictive motives, nor without a *bonâ fide* belief in the accuracy of his diagnosis; but for all that, if the evidence before us can be relied upon, he showed a lamentable want of forethought and discretion, both in the first instance and afterwards, when his position was shown to be untenable. He ought to have carefully weighed every available fact, and acted with the greatest caution before venturing to give an opinion which would, in all likelihood, destroy the happiness of a home and leave the hapless husband under the stigma of immorality. It was to be regretted that the case was allowed to proceed to trial, but we are glad to state that the plaintiff allowed a juror to be withdrawn.

THE LIVERPOOL LUNACY CASE.

ON the 4th inst., in the Nisi Prius Court, before Mr. Justice Cave, the case of Good *v.* Whittle and others, which excited considerable interest, came on for hearing. The plaintiff, Mary Good, a Liverpool lady, brought an action for libel and conspiracy against Dr. Ewing Whittle and his son, Dr. Glynn Whittle, of Liverpool, and Drs. Richard Hutchinson and George William Mould, of Manchester. The libel complained of was the medical certificate of the defendants certifying that the plaintiff was of unsound mind, and on the authority of which she was locked up in a lunatic asylum at Cheadle; and the second ground of action was alleged conspiracy on the part of the doctors. The first three defendants were charged with having improperly given certificates of insanity, in consequence of which the plaintiff was confined in a lunatic asylum at Cheadle; and Dr. Mould, who was the keeper of the asylum, was charged with having received the plaintiff into the asylum on certificates which it must have been within his knowledge were insufficient. At the conclusion of the hearing, which was of great length, and in the course of which fourteen medical men were examined—four for the plaintiff and ten for the defence,—the jury, after two hours' consultation, returned a verdict for the defendants on all the questions submitted.

A STRANGE CASE OF MANSLAUGHTER.

A YOUNG woman, aged seventeen, has been charged with wilful murder and convicted of manslaughter, for killing a child, by tying a scarf round its neck to stop its crying while she was wheeling it before her in a perambulator—and at the time reading a book—so tightly that it died. We cannot but regard this as a case of more than common concern. It seems to us to point to a matter of the highest moment. Beyond question this young woman was so engrossed with her book that her intelligent will was suspended. The work she was reading was doubtless a novel of some exciting kind, and she was so affected by it that she could not either tolerate the interruption caused by the crying of the poor little child, or exercise a rational judgment as to what she did or had done to it. Unhappily, the mischievous effects of sensation literature are only too apparent throughout the population. A few days ago a boy hanged himself while trying to *realise* the description of an execution which he had been reading. It matters little whether the books read be good or bad in their aim; it is the fact of taking the mind out of its natural relation with the world of fact and placing it in the midst of a fictitious world that does the harm. Not only are the results of this distraction of the consciousness occasionally disastrous in regard to the occurrences of life—as in the instance to which our attention is now especially directed,—but serious injury is done to untrained minds by throwing them into a state which approximates to hypnotism. To read a novel, living and feeling in the scene it pictures to the mind, and at the same time to attend to the actual surroundings, without a very great strain, is impossible. Even practised readers know how, being engrossed with a subject of thought, they forget the scene around them. An untrained brain may do more than forget it; may become disordered in the endeavour to do two things at once. It is desirable to lay stress on cases like this. We are not prepared to say that this young woman ought to have been more severely punished, because, unless the evil nature of her crime were made plain, no deterrent effect would be produced by a heavy sentence. The offence was reading when engaged on duty. The manslaughter was an outcome of this fault. We do not suppose the convict had the slightest animosity to the child, and it is not necessary to suppose that she was of a particularly brutal or cruel disposition. It may be quite true that she does not remember what occurred. Her consciousness was busy with the book; what she did to the child was done with a half consciousness that busied itself only with results. The lesson to be learnt is one of public and domestic prudence. Servants and children should never be allowed to read while engaged in any sort of work. Divided attention involves mental distraction, and "derangement" may at any moment supervene.

INSTRUCTIONS AGAINST CHOLERA.

EVERY sanitary authority ought now to issue plain directions to householders, giving practical formulæ for disinfecting solutions, &c. Several circulars and pamphlets to this effect have reached us, all of which are very good. But some of them are vague, and do not give particulars. Among the best are—Precautions against Cholera, by Dr. J. Spottiswoode Cameron, medical officer of health for Huddersfield, printed by J. Broadbent and Co., of that town; Plain Instructions to Heads of Families and others, issued by the National Health Society, 44, Berners-street, to be had from Allman and Son, 67, New Oxford-street, at rates which only cover the cost of printing. Every parish or sanitary authority, we repeat, should feel responsible for sending such instructions to each householder, and for supplying gratuitously or on low terms solutions of the disinfectants recommended.

MICROBE AND MACROBE.

M. SEDILLOT, of the Académie de France, having discovered, or fancied he discovered, in 1878, a very minute organism of correspondingly short life, designated it a microbe. Exception was taken to the term on philological grounds; so he consulted M. Littré, and on Feb. 13th of that year, he received from the illustrious physician, Hellenist, and lexicographer the following reply: "Microbe and microbie are quite good words. To designate the animalcules I would give the preference to microbe: first, because it is shorter; next, because it reserves microbie, a feminine substantive, for the designation of the state of microbe." In another letter, dated May 13th of the same year, M. Littré adds: "It is quite true that *microbi* and *macrobi* signify in Greek short life and long life; but, as you justly observe, the question is not one of Greek, properly so called, but of the use our scientific language makes of Greek roots. Now the Greek language has *βίος* (life), of which the root may very well figure under the *be* or *bie*, with the sense of living, in *acrobie*, *anacrobie*, *microbe*. My feeling is not to reply to criticism, and let the word defend itself, which it will doubtless do." M. Sedillot, however, had afterwards to be told that, nearly a quarter of a century before him, Filippo Pacini, of Florence, had published in the *Gazzetta Medica Italiana* a demonstration of the minute organism in question, which (with all deference to M. Littré) he called by the still more exact name of "microbio," and had connected it with cholera as the proximate cause of that malady—the

Digitized by Google

"microbio colerigeno" (*vide* THE LANCET, August 2nd, 1884, p. 203). Macrobe, on the other hand, was in literary use and acceptation centuries before it received any pathological meaning—having been employed by Pomponius Mela, the Roman geographer, to designate a long-lived race of Ethiopians. What reader of Rabelais, moreover, has forgotten the title of Macrobio applied by the satirist to the aged chief of the inhabitants of one of the numerous islands on which Pantagruel and Panurge landed?

THE ISOLATION OF INFECTIOUS DISEASES AT BRISTOL.

A CIRCUMSTANCE is attracting attention at Bristol which indicates some error in the sanitary arrangements of the city. A child alleged to be suffering from fever has been refused admission into the hospital for infectious diseases belonging to the sanitary authority because that building is being reserved for cholera cases; in other words, a case needing isolation is not received merely because some other case also needing it may perhaps occur. This is by no means the first time that this anomaly has existed in Bristol, for we have more than once noticed that whilst scarlet fever was spreading fatally in the city, the hospital has been kept empty, professedly in case small-pox should be imported. If it be a fact that Bristol is so backward as to have made provision for one disease only, surely the disease which is actually present should not be allowed to spread for the sake of another which may never appear at all. The true remedy for Bristol will be that the city should provide ward pavilions for at least two current infectious diseases occurring in both sexes, and that it should also maintain an isolation building for any special emergency. Bristol has hitherto done but little towards preventing the spread of its current infectious diseases by isolation, and the reason doubtless is that it has not provided itself with adequate means for carrying out this important sanitary measure.

EXPENDITURE IN ABERDEEN INFIRMARY.

THE managers of this infirmary have unanimously adopted the report of a committee which has been examining the expenditure with a view to its reduction. The principal recommendations of the committee have reference to making a reasonable charge for domestic and private servants, reminding patients who can pay of the duty of contributing something to the hospital, and suggesting strict supervision of internal administration. One remark surprises us, that "there are undoubted prodigality and waste, chiefly in what is supplied to out-patients." We believe the London experience to be that very little is spent, much less wasted, on out-patients. A table is given of the respective cost for certain articles in Aberdeen and Dundee, there being about forty more patients daily in the Aberdeen Infirmary. The cost for wine, spirits, and porter in Aberdeen was, for 1883, £283; in Dundee, £62.

SALT AS A PREVENTIVE OF CHOLERA.

A RESPECTED correspondent, styling himself "Vigilans," has sent us a lengthy communication on this subject, which was fully discussed in the Indian papers about twenty years ago. Some valuable evidence as to the physiological value of salt was adduced by Mr. F. C. Brown, of Anjarikandy, in Malabar. This gentleman asserted that while cholera was devastating the surrounding districts not one fatal case occurred amongst the labourers on his estate. This freedom from the scourge was attributed by him solely to the fact that his men were allowed salt without stint; and so far as could be ascertained, no other circumstance was present to participate in the result.

THE FLY PLAGUE.

THE long spell of hot weather we have experienced has not been without its disadvantages, and among these must be mentioned the annoyance caused by flies to both man and beast. Horses have more especially suffered, and their sufferings have been rendered all the more general and acute from the stupid and useless mutilation to which they are subjected in being "docked." This consists in the very painful operation of chopping off more or less of their tail, cutting through the coccygeal bones, muscles, nerves, and bloodvessels, and for ever after depriving the horse of one of its beauties and most useful defences against insects, to whose attacks it is very much exposed. This fashionable mutilation, the result of a depraved taste, has now become so common, that, whereas a few years ago very few horses had to undergo it, there is scarcely one to be found which has not had one-half or two-thirds of its tail lopped off by the horse-dealer, roadside farrier, or veterinary surgeon. Consequently, the agony endured from the operation is trifling in comparison with that which horses experience from the flies, against which they have no protection when subjected to this unreasonable and damaging curtailment. Various expedients have been resorted to, with the view of driving away these troublesome insects, and some of them are worth a trial, as they are likely to be successful. Paraffin, petroleum, or a strong solution of carbolic acid or carbolised oil, may be applied to the hairs of the forelock, mane, and tail, or bits of sponge or woollen cloth saturated with these and attached to the bridle, collar, and crupper strap may be used. A solution of Macdougall's sheep dip answers well when sponged over the skin, as does also Jey's disinfecting fluid. People who ride or drive, or who commiserate their horses when in fly-haunted stables, might advantageously resort to something of this kind, should the creatures suffer from the folly of fashion in being deprived of their tails.

BITE OF A RAT.

IN medicine there are very few pathognomonic symptoms. This statement is equivalent to saying that many diseases present pretty much the same symptoms. Hence the proverbial difficulty of diagnosis. Whether some phenomena observed by M. Millot-Carpantier were really or apparently those of rabies must remain doubtful. A patient's hand was bitten by a rat; the resulting wound completely healed at the end of fifteen days, but was followed by a painful swelling of the forearm, attended with fever, which also passed away; in another fifteen days a purpuric eruption appeared, which also in its turn was succeeded by certain strange nervous symptoms resembling those of hydrophobia. The neurosis lasted for a month, after which the patient remained in good health.

REDWATER.

THIS disease of cattle has been studied by Dr. Berry and Mr. Hutcheon, and is regarded as an infectious disease, which spreads through the medium of the food or drink contaminated by the droppings of the infected animals. The period of incubation is said to be fourteen days. The urine in a well-marked case is of a port-wine colour, and becomes almost solid with heat. No red blood-discs are seen in the urine when the microscope is employed. The condition of the urine (hæmatinuria) generally lasts four or five days, and is very fatal. The spleen becomes greatly enlarged, softened, and diffluent. A bacillus has been detected in the blood of the spleen, which has been named bacillus hæmatinuriæ. The microbe was demonstrated by drying in the air a thin film of blood on a cover-slip. A drop of glacial acetic acid is allowed to remain on the film for a few seconds. After this the cover-

Digitized by Google

slip is washed in distilled water, then dried again over the flame of a spirit lamp; next floated for four minutes on a few drops of warmed "gentian-violet" or "amaranth"; washing in rectified spirit, drying, and mounting in Canada balsam complete the essential part of the process for demonstrating the bacillus, which is shorter and thicker than bacillus anthracis. No bacilli were found in the urine.

THE LATE PROFESSOR FRANCESCO CORTESE.

THE fellow-townsmen of this distinguished head of the Army Medical Department of Italy, whose death in Rome last October was the subject of a notice in THE LANCET, have just raised to his honour, in Treviso, Province of Venetia, a memorial tablet, placed in the façade of the house in which he was born. The inscription, a translation of which we subjoin, is from the pen of Senator Tommaso Vallauri, the most proficient of contemporary Italian latinists: "In this house was born, on the 12th of February, 1802, Francesco Cortese, who, as Professor of Anatomy in the University of Padua, shed lustre on the chair by his lectures and his writings; as army-surgeon, in the War of Independence he deserved nobly of his country; and having risen to high honour, he obtained the supreme rank of head of the medical staff in the Italian army. He died in Rome, to universal regret, on the 24th of October, 1883. To perpetuate the memory of their illustrious fellow-citizen the Town Council of Treviso placed this stone."

BOOKS FOR HOSPITAL PATIENTS.

An appeal has been made on behalf of the patients in the City of London Hospital, Victoria-park, for books or periodicals of a wholesome and interesting kind. Reading is the form of mental diversion to which educated people most naturally turn, and if this is the case in health when so many other amusements are possible, it is doubly so during sickness and convalescence when quiet is as needful as change is tantalising. Parcels must be prepaid. Donors of books will readily understand that the small charge on carriage, which is as nothing to each of them, may during the construction of a small library amount to a deduction neither handsome nor charitable from the already taxed resources of a hospital. Is it hardly necessary to add that no hospital or infirmary is so overstocked with literature at the disposal of patients, but that the want expressed by the City of London Hospital is felt in it also.

WOOLSORTERS' DISEASE.

We are glad to learn that on the 8th inst. a conference was held at the Bradford Town Hall between the employers and the employed of those engaged in the worsted trade, and the sub-committee of the Bradford Sanitary Committee, to draw up a code of regulations for the prevention of woolsorters' disease. The proposed regulations, after some modifications, were unanimously adopted; and a very good feeling of reciprocity was displayed between the masters and the men on the subject, the former expressing their readiness to adopt any measures to prevent infection amongst their employés.

CHOLERA AND RAGS.

A NEW order has been issued by the Local Government Board prohibiting, until the 15th of September next, the importation, or delivery for exportation, of any rags from France, unless the rags have previously been proved to the sanitary authority not to have come directly or indirectly from any infected place. All rags contravening the order may be destroyed on the advice of the medical officer of the port.

A LARYNGEAL NEUROSIS.

A FORM of laryngeal neurosis, which is probably not widely known, has been treated of some months ago by Dr. McBride, and still more recently by Dr. Russell in the *Birmingham Medical Review*. Charcot has recorded the notes of four cases, and he regards the affection as a laryngeal vertigo analogous to Menière's disease, the afferent path being the superior laryngeal nerve. The main features of the attack is a sudden falling on the ground, immediately preceded by a short dry cough, and sometimes by spasmodic breathing; unconsciousness has been more frequently observed than not. Subjectively, the patient is almost always annoyed by a tickling or burning sensation in the larynx. Some local hyperæmia, or a "granular" condition of the throat, is nearly always present, and marked benefit has been derived from local medication and the internal administration of bromide.

THE HEALTH OF IDIOTS.

DR. SHUTTLEWORTH'S paper on "The Health and Physical Development of Idiots as compared with Mentally Sound Children of the same Age" is full of significance, and will be perused with much interest. We cannot, however, withhold the expression of a wish that the author had occupied himself more practically with the question how far the health and physical development of idiots throw light on the causation of their mental disability. It is not so important to them whether idiots die earlier or live longer than some children of their age, as it is to ascertain by the study of vital statistics and by the investigation of physical facts, whether preventable disease contributes to the production of idiocy. The value of Dr. Shuttleworth's paper is great, but it would have been still greater if it had dealt more directly with the subject of physical causation.

THE CHOLERA.

AT the time of going to press, we are glad to be able to state that we have not received a report of the occurrence of a single case of Asiatic cholera in any of the London hospitals, or in any part of England, Scotland, or Ireland.

ON the 8th inst., Mr. Durham performed an amputation at the left hip-joint, in the theatre of Guy's Hospital, on account of extensive epitheliomas of the thigh and buttock. The operation lasted about twenty minutes, during which time the common iliac artery was compressed by Mr. Rich Davy, and very little blood was lost. The man, however, never rallied, and died twenty-four hours after. The rectum was carefully examined; there was no abrasion of its mucous membrane, nor blood in the bowel; only a small spot of arborescent capillary injection was seen in the submucous coat at a point about ten inches from the anus. In the above operation the use of the rectal lever was exemplified.

MESSRS. WEISS AND SON have just made for the Hon. James White, M.L.C., a magnificent surgical instrument case for the Prince Alfred Hospital, Sydney. It is made of the choicest mahogany and plate glass, is all of the very best workmanship, and will form a handsome feature in any operating theatre.

THE Indian medical journals announce the death of T. K. Rogers, Indian Medical Service, which took place in Madras on June 12th, from typhoid fever. The deceased had entered the service in 1877, and was Professor of Chemistry in the Madras Medical College and Chemical Analyst to the Government of Madras.

Digitized by Google

IN response to an appeal by the vestry of St. James's, Westminster, that the Government should introduce legislation conferring on local authorities a general power of control over the erection and maintenance of overhead wires, a letter has been received from the Local Government Board, stating that it would be impossibla to deal with the subject by legislation this session, and the Government cannot now say what Bills they will introduce next session, but there would probably be an advantage if a Select Committee were appointed to inquire into the subject, and the Board will consider whether steps should be taken early next year with this view.

ON the 8th inst., in the House of Commons, Sir Charles Dilke stated that the Local Government Board are not at the present time in possession of precise information as to the cost now being incurred in deodorising the sewage of London. Permanganate of potash has not been used to any considerable extent, only between three and four tons having been delivered, at a cost of about £130 per ton. Between July 10th and August 1st, perchloride of lime, to the extent of, on an average, about thirty tons per day, has been mixed with the sewage discharged at Crossness and Barking, the price of chloride of lime being about £9 per ton.

THE Sanitary Institute of Great Britain are making an effort to bring together the official reports and papers of the late Dr. Farr, and intend publishing them by subscription if a sufficient number of subscribers should come forward to justify the expense. Mr. Noel Humphreys, F.S.S., of the Registrar-General's Department, has been entrusted with the selection and editorship.

THE death of M. Bouisson has been recently announced. He was born in 1813, and finished his medical studies in 1836. He was appointed Professor of Physiology in Strasburg in 1837; of External Pathology in Montpellier in 1840; and of Clinical Surgery in 1851. In 1859 he was elected to the Chair of Operative Medicine, which he held until his death.

BY the death of Sir Erasmus Wilson, the Royal College of Surgeons, as residuary legatee, will, says *The Times*, receive a sum of something like £180,000, whilst the funds of the Royal Medical Benevolent College, the Medical Benevolent Fund, and the Sea-bathing Infirmary, Margate, will benefit to the extent of £5000 each.

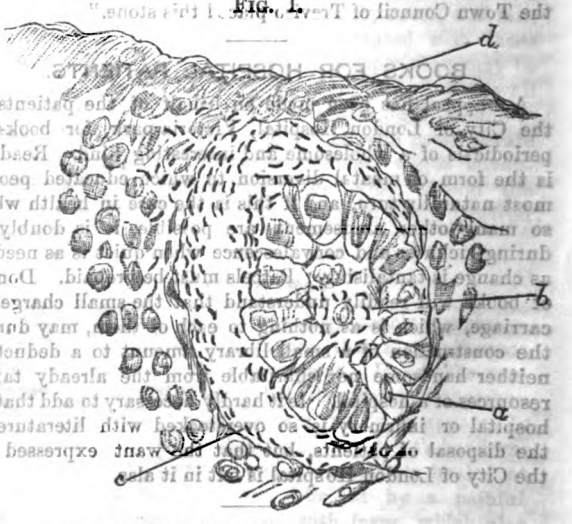
THE gentlemen with whom Drs. Klein and Heneage Gibbes will co-operate in their researches into cholera are Dr. D. D. Cunningham, Professor of Physiology at the Calcutta Medical College, and Surgeon-General J. M. Caningham, Sanitary Commissioner with the Government of India.

TO avoid inconvenience and delay which might be experienced by Poor-law medical officers, we are asked to state that Dr. Rogers, President of the Poor-law Medical Officers' Association, has removed from Soho-square to 31, Montague-place, W.C.

WE remind our readers that the Bradshawe Lecture will be delivered by Dr. G. H. Philipson, of Newcastle-on-Tyne, on Monday, the 18th inst., at 4 o'clock, at the Royal College of Physicians.

THE Canadian medical journals announce the death of Dr. J. E. Landry, for more than a quarter of a century Professor of Surgery in Laval University, Quebec.

DEPUTY SURGEON-GENERAL TRIMNELL, late of the Madras Army, fell dead on the beach at Jersey on the morning of the 9th inst., as he was about to enter the sea to bathe. He had only recently arrived in the island to attend the funeral of a relative.



THE meeting of the Canadian Medical Association will be held this year at Montreal on the 25th, 26th, and 27th inst.

DR. KOCH ON THE CHOLERA.[1]

(Continued from p. 250.)

THE conference upon Cholera at the Imperial Board of Health in Berlin, on the close of Dr. Koch's address, which we reproduce in abstract below, adjourned till July 29th, when it was occupied with several questions arising out of the discovery of Dr. Koch, upon which he made further observations. We hope later to give an outline of this meeting, which is reported verbatim in a supplementary issue of the *Berliner Klinische Wochenschrift*, Aug. 11th. Before giving the continuation of Dr. Koch's address we may draw attention to the subjoined figures, selected from a series of illustrations which have been published in the Berlin journals. They illustrate points in the morphology and growth of the bacilli detailed last week. Fig. 1 is a

FIG. 1.

preparation from the intestine of a cholera patient, showing a Lieberkühn's gland, (*a*) in transverse section; within the gland (*b*), and between its epithelium and basement membrane (*c*), are seen numerous comma bacilli. At *d* is the surface of the mucous membrane denuded of epithelium. Fig. 2 is a cover-glass preparation from the margin of a drop

FIG. 2.

of meat infusion with pure cultivation of common bacilli. At *a* are seen long condensed filaments developed from the

[1] For the full text of Dr. Koch's address, see Berliner Klinische Wochenschrift, Aug. 4th and 11th, and Deutsche Medicinische Wochenschrift, Aug. 7th, 1884.

Digitized by Google

bacilli. Both figures are from preparations magnified 600 diameters. Dr. Koch's address continues as follows:—

Being thus convinced as to the distinctive characters of the common bacillus, the next thing was to determine the relation in which it stands to the cholera process, and whether it ever occurred in non-choleraic cases. In the ten examinations made in Egypt this point was only tested microscopically, no cultivations having then been made. In India the intestines were examined in forty-two cases, both microscopically and by cultivations, and in not one was the bacillus absent; in very acute cases it was found almost unmixed. Choleraic dejecta from thirty-two cases yielded similar results, but in only two out of many observations on vomited matter were bacilli found. It was probable that in these two cases the vomit contained fæcal matter. Bacilli were also found in specimens from eight cases sent by Drs. Kartulis and Schiess-Bey from Alexandria, and in two cases examined at Toulon in conjunction with Drs. Strauss and Ronx, and in the choleraic dejecta of two other cases. One of these Toulon cases was that of a sailor attacked with cholera when convalescing from malarial fever; he died four hours after the seizure, and the autopsy was made half an hour after death, it being always an object to make such an examination as soon as possible. In this, as in other acute cases, the intestines contained almost a pure growth of the comma bacillus. The other Toulon case was similar; but in neither was the microbe found by Strauss in Egypt detected in the blood. Thus the comma bacillus has now been found in nearly one hundred cases of cholera, occurring in a constant relation to the cholera process, being most abundant in the lower end of the ileum, where the changes are most intense, and being most pure in the acute uncomplicated cases. On these grounds the comma bacillus may be considered as specific to cholera. Many observations were made in other diseases, and in subjects who had recently passed through attacks of cholera, without finding these bacilli in the dejecta or in the bowels. These observations included cases of dysentery, typhoid fever, bilious typhoid, and infantile diarrhœa; the secretions of the mouth, which are so rich in bacterial life; the intestines in arsenical poisoning; but, although bacteria of all kinds were met with, the comma bacillus was conspicuous by its absence. Similar negative results followed examination of the drain-water of Calcutta, and the impure tank-water in the villages on the banks of the Hooghly. Once only in the water flooding the region of the salt-water lake east of Calcutta was a bacterium found at first sight resembling the cholera bacillus, but on further scrutiny it proved to be thicker, and not to have the power of liquefying gelatin. In his own experience and that of other bacteriologists a similar form to the comma bacillus was unknown. Three different views as to its relation to the cholera process are tenable. (1) That the disease favours the growth of these bacilli by affording them a suitable soil. If so, it would mean that the bacillus in question is most widely diffused, since it has been found in such different regions as Egypt, India, and France; whereas the contrary is the case, for the bacilli do not occur in other diseases, nor in the healthy, nor apart from human beings in localities most favourable to bacterial life. They only appear with the cholera. (2) It might be said that cholera produces conditions leading to a change in form and properties of the numerous intestinal bacteria—a pure hypothesis; the only instance of such a conversion refers to a change of physiological and pathogenic action, and not of form. Anthrax bacilli under certain conditions lose their pathogenic power, but undergo no change in shape; and that is an instance of a loss of pathogenic properties, whilst there is no analogy to support the view of the harmless intestinal bacteria becoming the deadly cholera bacilli. The more bacterial morphology is studied, the more certain is it that bacteria are constant in their form; moreover, the comma bacillus retains its special characters unchanged through many generations of culture. (3) Lastly, there is the view that the cholera process and the comma bacilli are intimately related, and there is no other conceivable relation but that the bacilli precede the disease and excite it. "For my own part," said Dr. Koch, "the matter is proved that the comma bacilli are the cause of cholera."

If this be so, experimental confirmation of the fact might be expected; and, were authors to be trusted, there should be no difficulty in this, since it has been stated that cholera occurs in cattle, dogs, fowls, elephants, cats, and other animals. But there is no evidence of such animals being spontaneously attacked with the disease during cholera prevalence; and direct experiments have either proved negative, or, if positive, have been inconclusive or been contradicted by others. The experiments of Thiersch on white mice, to which so much importance has been attached, have been repeated by Koch with recent and with decomposing choleraic material, the mice remaining unaffected. Experiments were also made upon monkeys, cats, fowls, dogs, and various other animals, but nothing like a cholera process was observed; and a similar result followed experiments with the comma bacillus in all stages of its development. Animals were fed with large quantities of the comma bacillus, with the result that the bacilli were found to be destroyed in the stomach, none appearing in the intestinal canal. It is not so with other bacteria—e.g., a red micrococcus found in Calcutta. Dr. Barclay fed mice with this micrococcus, and obtained cultures of it from the intestinal contents. The bacillus was injected directly into the small intestine and into the large bowel of monkeys, but without result; nor was any better success obtained by such measures employed after irritants had been introduced into the intestine. The only experiment which at first seemed to promise results was when pure cultures were injected into the blood of the rabbit or into the abdominal cavity of the mouse. The rabbits became very ill after the injection, but recovered; the mice died in from twenty-four to forty-eight hours, and the comma bacillus was found in the blood. It would seem as if, unlike other experiments on infective disease, very large quantities of the virus had to be employed; but to assure himself of the capability of infecting animals with cholera, Koch made special inquiry as to whether animals in India ever had the disease. He learnt that in the densely-populated province of Bengal, where many kinds of domestic animals are to be found under conditions favourable for infection, cholera was unknown among them. They appear to enjoy an immunity, and are incapable of being experimentally infected—a fact which is not fatal to the view that the comma bacillus is pathogenic; for, apart from experimentation, no other explanation of its connexion with cholera is possible than the causal one. Leprosy is not communicable to animals, and yet the lepra-bacillus must now be regarded as the cause of the disease. It is probably the same with typhoid fever, which is not communicable to animals. It is enough to ascertain the constant occurrence of a special kind of bacterium in a disease, and its absence in other diseases, its occurrence corresponding with the pathological lesions and the course of the disease. And there are some animal diseases not transmissible to man—e.g., rinderpest and pleuro-pneumonia. Parasites have their special hosts; many kinds of animals have their own tapeworm, which cannot develop in any other. Again, there is a whole group of diseases, especially the exanthemata, conceivably dependent on micro-parasites; but no one has ever yet shown that a disease can produce a specific organism. In cholera we have instances amounting to actual experimental infection of man—e.g., the infection of those who are engaged in washing linen soiled by choleraic dejecta. Such linen contains the bacilli often in a pure form, and if infection occur through this medium, it must be by means of the comma bacilli, the only micro-organism present. The hands may be soiled and the bacilli introduced into the mouth by direct contact or through the food, or drops of the washing water may come in contact with the lips, and thus in some way the human being is fed with a small quantity of a pure culture of comma bacilli. Another instance was found by Koch in the case of a tank of which the water was used for drinking and other purposes by many people among whom cholera was raging. He found the comma bacilli in this tank, and learned that the linen of the patients was washed in it. Around the tank were some thirty or forty huts, inhabited by 200 or 300 people; of these seventeen died, the number taken ill not being ascertained. The tank also received the refuse from the dwellings. The Hindoos bathe in the tank, wash their utensils in it, and deposit excreta on its shore; and if a hut has a latrine, its outflow is into the tank. Now, it was found that after a time the bacilli became less abundant in this water, and coincidentally the cholera declined; whereas, had the epidemic been the cause of their presence, and not the result, the number of bacilli should have increased in it. The whole etiology of cholera suggests the view taken as regards the comma bacilli. They multiply rapidly, soon reach their term, and are supplanted by other bacteria. So in the intestine they multiply, set up irritation and diarrhœa, and all the typical symptoms of

Digitized by Google

the choleraic seizure. Under normal conditions—in animals at least—the bacilli are destroyed in the stomach, and this harmonises with the important part played by predisposition, and the liability of those to be attacked who are suffering from gastric or intestinal catarrh, or who have overladen the stomach with undigested food, conditions which would facilitate the passage of the bacilli unchanged into the intestine. But the bacillus is limited to the intestine; it is not found in the mesenteric glands or in the blood. How, then, can it destroy life? Probably from the production of a poisonous substance, such as is produced by bacteria in putrefaction. In a gelatin culture of the comma bacilli with which blood-corpuscles were mingled, the corpuscles became destroyed as the colony grew, and it is probable that the bacilli exert a like destructive influence on other cells. That some poison is produced gets confirmation from the experiments of Dr. Richards of Goalundo, who fed pigs with choleraic material, death ensuing from convulsions in from fifteen minutes to two and a half hours. This must have been due to "intoxication," and not, as Dr. Richards states, to choleraic infection, for another pig, fed on the intestinal contents of one of those so killed, remained healthy. If it had been choleraic virus, it should have been transmissible. These experiments prove that in cholera the dejecta contain certain substances poisonous to swine, whereas dogs, mice, and other animals are unaffected by it. Assuming that the bacilli produce a specific poison, the phenomena of cholera may be thus explained. The poison acts locally in destroying the mucous membrane, and, being absorbed, it acts generally, and especially paralyses the circulatory organs. All the symptomatology of cholera, usually considered as due to the loss of water and thickening of the blood, is explicable on this view. Death may occur in this stage of cholera-poisoning when but few local changes are found, and the intestinal contents exhibit a pure culture of bacilli. If this stage be passed through, there occur necrotic changes—hæmorrhages and putrefaction—with symptoms due to the absorption of putrefactive products, usually described as cholera-typhoid. And there is abundant evidence of the cholera virus occurring in the dejecta, and rarely in the vomit. For the further dissemination of the disease it is necessary that the dejecta should be retained in the moist state, for drying destroys their potency; and this fact is borne out by the spread of the disease through the water-supply, or more directly by soiled hands, or even conveyance through insects, or blow-flies to food. Drains may be infected, and through them the water-supply. As the virus cannot be retained in the dry state, aerial infection seems impossible; nor has cholera ever been conveyed by merchandise or by letters, even if these are not disinfected and fumigated. Cholera can only be spread by human intercourse—a fact sometimes wanting in proof because it is overlooked, for the mildest case may be as infective as the most severe. The diagnosis of such mild cases by the detection of the comma bacillus becomes thus of much importance.

That the virus can be reproduced and multiplied outside the body is apparent, since the bacillus can be cultivated artificially, and its growth is not affected by comparatively low temperatures. Probably it does not grow in streams and rivers, where, owing to the current, a sufficient concentration of nutrient substance does not occur; but in stagnant water and at the mouths of drains &c.; vegetable and animal refuse may accumulate and afford the necessary nutriment. Thus is explained the propagation of cholera by the subsoil water, and the increase of epidemics with the sinking of its level, which lessens the flow and diminishes the amount of surface water. Admitting the dependence of cholera upon this micro-organism, it is impossible to conceive the disease having an autochthonous origin in any particular place; for a bacillus must obey the laws of vegetable life, and have an antecedent; and since the comma bacillus does not belong to the widely diffused micro-organisms, it must have a limited habitat. Therefore the occurrence of cholera on the delta of the Nile does not depend on its resemblance to the delta of the Ganges; but the disease must have been imported there as it is into Europe. It was once thought that an outbreak in Poland had a local origin until it was discovered to have been introduced from Russia. Again, about ten years ago, there was a sudden outbreak at Hamar (Syria), thought to be an instance of local origin, but erroneously, as shown by a statement of Lortet, who told Koch, when at Lyons, that the epidemic had been introduced into Hamar, where he was at the time, by Turkish soldiers from Djeddah. Indubitable instances of local epidemics arising outside India are not known, and everything confirms the view gained by experience that the cholera is due to a specific organism having its home in India. It used to be thought that the disease had started from Ceylon, Madras, or Bombay, but there is now general concurrence in regarding Bengal, the delta of the Ganges, as the original source. This is the only region where the disease never varies from year to year, for although some other regions, as Bombay, are never free from it, yet it is highly probable that this is due to its continued re-introduction. The upper region of the Ganges delta is thickly populated; the lower district, Sondarban, covering an area of 7500 English square miles, is uninhabited, and here the Ganges and Bramahpootra break up into a network of watercourses. The district abounds in luxuriant vegetation and in animal life, and is the seat of inundations and the home of pernicious fevers. Here it is probable, where the vast amount of decomposing vegetable and animal life affords a suitable soil, that the cholera bacillus flourishes. All great epidemics begin with an increase of cholera in South Bengal. The inhabitants of Lower Bengal dwell in huts raised on mounds to protect them against inundation, the excavations thus formed making the so-called "tanks," which are very numerous in the district of Calcutta and its vicinity. Since 1870, when new drainage works and water-supply were introduced, the mortality from cholera in Calcutta has become much reduced; but the retention of many of these tanks and the nature of the native dwellings still account for the spread of the disease. A remarkable instance of the disappearance of cholera under improved water-supply is afforded by Fort William, which used to have many cases annually. Other Indian towns show the same good result of improved water-supply—e.g., Madras, Bombay, and Pondichery, where some years ago the formation of artesian wells banished cholera; and although cases reappeared there last spring, Dr. Farnell of Madras ascertained that the cases were limited to the part of the town not yet supplied with these wells. Although contamination of drinking water may be the chief mode of spread, this is not the only way, and each place has its own conditions, which have to be dealt with. The diffusion of cholera in India depends on human intercourse, especially on pilgrimages, which are carried on to an inconceivable extent—e.g., hundreds of thousands flock yearly to Hurdivar and Pari, remain there many weeks herded together, bathing in the tanks that supply them also with drinking-water. Over the borders of India the cholera is carried into Persia, and in the old caravan days thence to the south of Europe; but the route now is by the Red Sea and Suez Canal. Every year the danger to Europe by this route increases, for Bombay, which is seldom free from cholera, is but eleven days distant from Egypt, sixteen from Italy, and eighteen or twenty from France. It is also clear that the greatest danger lies in ships carrying large numbers of people, as troops, pilgrims, coolies, and emigrants, and not the merchant vessels with small crews, for in the former the outbreak of an epidemic would be likely to last till Europe was reached. In the reports of the Sanitary Commissioner of India, 1881, it is stated that out of 222 coolie ships, carrying from 300 to 600, which had left India for American colonies in ten years, thirty-three had cholera on board, and in sixteen the epidemic lasted more than sixteen days. Why outbreaks of cholera outside India die out is probably due to different factors. One is that an attack of cholera confers immunity at least during the period of one epidemic, and whole districts may enjoy a similar immunity for a time; cholera having been in the place one year, passes it by in the next. Another is that the bacilli do not pass into the "resting state." And a third is the check given to their development by temperatures below 17° C.

In conclusion, Dr. Koch adverted to the subject of treatment, and reminded those who say that such discoveries do not enable us to cure the disease better than formerly, that a rational treatment of most diseases, and especially of infectious diseases, cannot be adopted until their cause and nature are known. But even yet the discovery of the cholera bacillus is important, as furnishing an aid in diagnosis which would facilitate the detection of the first case occurring in a district, and the adoption of measures to prevent its spread. Knowing also the nature and properties of the bacillus, and especially the readiness with which it is killed by drying, the right direction of prophylaxis is assured and the lavish expenditure of disinfectants checked, so that there will not be a repetition of what happened in the last epidemic, when millions of gallons were poured into the gutters and sewers

Digitized by Google

without the slightest need. Even therapeutically the knowledge of the comma bacillus may be of value. Diagnosis will be possible in mild cases and in the early stages of the disease, when treatment is of most avail.

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

THE Congress at Copenhagen, which was formally opened on the 10th inst. at the Industrial Exhibition, was preceded on the evening of the 9th by a reception and conversazione in the Tivoli Hall, which was attended by about 1200 members. There were present at the opening the King and Queen of Denmark, the King and Queen of Greece, and the whole of the Royal Family, the Corps Diplomatique, the President of the Rigsdag, the representatives of science and of the University, and the members of the Congress. The Danish professor, Dr. Panum, delivered an address welcoming the foreign representatives to Copenhagen, to which Sir James Paget, Professor Virchow, and Dr. Pasteur replied. Professor Panum was elected president; and Professor Axel Key (Stockholm), Dr. Dahl (Christiania), and Dr. Hjelt (Helsingfors) were nominated Scandinavian vice-presidents. Sir James Paget, Sir William Gull, Sir William MacCormac, Dr. Henry Acland, Sir James Risdon Bennett, Professor Lister, Sir Spencer Wells, Dr. Erichsen, Dr. Watson, and Dr. Marshall representing England, were made honorary presidents.

On the 12th inst. Dr. Billings of Washington laid before the Congress the following invitation, bearing several signatures:—"On behalf of the medical profession of the United States, we, the undersigned members of a committee appointed for that purpose by the American Medical Association, have the honour to offer to the International Medical Congress an invitation to hold its next meeting in the city of Washington in September, 1887." A paper was read by Professor Crudeli, of Rome, on the Cause of Malaria, and the means of making the countries where it prevails more healthy.

The Congress includes 350 Danes, 100 Swedes, 100 Norwegians, and 800 representatives of other nations, figures which show that the attendance of foreign medical men is larger than was the case at the London Congress.

STRAY NOTES ON THE CONGRESS.

(By an Occasional Correspondent.)

Leaving my home in the Midlands by the four o'clock train last Thursday afternoon, I drove straight from Euston to Ludgate-circus, where a German clerk at Cook's counter noted my projected route, and told me my tickets would be ready if I returned after I had dined. This I did, all the more pleasantly in that good luck had begun to smile on me in a chance meeting with a capital travelling companion, Professor Berry Haycraft, also on the way to the Danish capital. Dinner over, tickets paid for, and luggage registered, we left Ludgate-hill station for Queenboro' punctually at 8.25. In due time, on board one of the fine steamers on this route, I, as a wretched sailor, fondly looked on the smooth water, without a ripple in the lovely moonlight night. So bright was the moon that the electric light at the masthead was let out as soon as the engines were set going. The vessel was crowded, but doctors were conspicuously few. No time was lost at Flushing, and on we sped at a very fair pace for a continental train. No Great Western or London and North Western runs beyond the Channel. A long and very hot dusty day through a flat country, with a forward and seemingly good harvest, brought us at 9 P.M. on Friday to Hamburg. Oh! what a scrimmage for our luggage! what banging about of the boxes and swearing of porters! It came to an end at last, and, after a short carriage-drive through the beautiful city, we found ourselves comfortably seated in the train for Altona and Kiel. At one of the changes Sir James Paget's ever kindly smile, word, and hand greeted us, and it was then no longer doubtful that, even if our countrymen at the Congress were not unanimous, old England was sure to walk to the fore. At Kiel were three beautiful and most comfortably-appointed Danish steamers ready to convey the Congress members to Korsör. The sea trip, about six hours, was delightful; the water as still as a mill-pond; and after a comfortable supper in the saloon we all enjoyed sleep in spacious and well appointed cabins. From Korsör, two and a half hours' rail brought us to the capital, in a few minutes over thirty-eight hours from London. I was much struck with the fertility and good farming of Denmark, and the generally prosperous look of the people. As through Holland and North Germany the day before, windmills were plentiful, reminding one of old England in the coaching days, and of France when the diligences of the Messagéries Impériale and of Lafitte and Caillard traversed the country. The cottages hereabout are mostly thatched, and the pigs and sheep well bred and fed. The corn is for the most part cut and carrying is forward. At the Copenhagen station was Sir Spencer Wells, genial as ever, moving off with his children and a load of luggage. On our right was a room with a notice on the door, "Medical Congress Bureau." Within it were colleagues, senior and junior, busy receiving us strangers with the most cordial affability and the most enviable polyglot facility. What capital English scholars these Danes are, alike in accent and idiom! Just before leaving home I had received a card of invitation to Kongensgarde 68. I had only just entered the reception bureau when my host made himself known, addressed me in excellent English, called forward his man-servant, who also speaks English, and on we drove to the most cheery and comfortable of homes. With all deference to Roman and Norman conquests, to Dutch William and the Huguenots, who certainly have been useful blood-crosses, I say that English and Danes are more alike than any other two nations. At any rate I felt so as my host showed me into my dressing and bath rooms. Oh! for that dip, after the hot, dusty journey! And a word, too, for the huge Turkish towels. Who does not remember the French washhand-basins with good big saucers, and the towels like pocket-handkerchiefs? They certainly do not do *these* things better in France.

As two o'clock was the time appointed for taking out tickets, &c., at the University, I devoted an hour, after a good breakfast, to visiting the Thorwaldsen Museum, which is a repository for the works of art bequeathed by Thorwaldsen to his native town, and is also his mausoleum, as it contains his tomb in the centre of a vast courtyard, round which are the galleries and rooms containing his works. Never did I see such a monument to the genius and energy and long-life devotedness of one man. At the appointed hour everything was ready at the University. With a lively remembrance of the great London Congress in 1881, I did not see how the great MacCormac could have a successor; but really, I think, Sir William has a most worthy one in Professor Lange, the secretary-general of this Congress. He has quite an army of willing and able juniors to assist him; but amongst these is a senior who deserves special mention, because not a member of our profession. He was working hard and most usefully in the reception-room. Capt. Richard Carstensen, of the Danish engineers, would, I think, astonish any linguist by his beautiful English. Everybody was at ease—not a hitch; tickets, programmes, maps, all in hand; and after a stroll and dinner, to which invitations were most hospitably plentiful, we made our way to the Tivoli Gardens' beautiful pleasure grounds, whose central hall was specially reserved for Friday evening as a reception- and lounging room for the members of the Congress. A cool breeze, sweet music, iced drinks, cunningly concocted light punch, and a Babel of tongues greeted one. I was glad to see Professor Esmarch looking very well and vigorous; and presently my fears that only English veterans would look in were disappointed, for I caught sight of two worthy representatives of young English medicine in Drs. Mahomed and Lambard Owen. After such a day and forty-four hours on the road, I was ready for bed.

The Sunday was not to be all rest, for that was the day appointed for opening the Congress. Still, time was allowed for attendance at the English church, or rather the service of the church, in a large room on the right of the yard in the Stormgade 21. Thanks to the efforts of H.R.H. the Prince of Wales, money enough has been collected to build an English church here, and it is hoped that the foundation-stone may be laid next spring by H.R.H. the Princess of Wales, who, if possible, is almost more popular here than she is in England. Lady Paget, Miss Paget, and one of her brothers, as also Sir Henry Acland, attended the service,

Digitized by Google

which was performed by the Rev. C. A. Moore, M.A., chaplain to H.B.M.'s Legation, the sermon being preached by the Right Rev. P. D. Titcomb, D.D., Bishop-Superintendent for the English chaplaincies in Northern and Southern Europe.

The word having been passed that visitors at the opening ceremony were to be in full dress, we had scarcely time to don our war paint, and be at the Palais de l'Industrie in the Vesterbrogade at 1 o'clock. The hall is beautifully proportioned and decorated, and upwards of 1200 visitors had assembled, when the Royal Family drove up in eight carriages. The scarlet liveries and the outriders made a fine pageant in the glaring sun; and the President, Professor Panum, might well feel proud when he opened the Congress from the tribune, addressing the Kings and Queens of Denmark and Greece, who were seated in gilded armchairs serene and stately before him. After the President, Sir James Paget spoke, as President of the preceding Congress; and I do no injustice to his compeers when I say he held his own as the first orator in the medical profession. Virchow followed; and then Pasteur, who received an ovation without parallel. His son is one of the secretaries at the French Embassy here; and when also I mention that President Panum addressed the assembly in French, that lively bird *le coq Gaulois* may be excused if he crowed rather loud for a day or two. The speeches over, a short interval was allowed before commencing any business (Sunday, remember). The Royal Family graciously utilised the time by chatting with the inner circle of visitors. The King of Denmark very pointedly picked out Virchow for several minutes' conversation, then chatted very jovially with Sir William Mac Cormac, passing on to Volkmann with rather more stateliness. His Majesty seemed to have bethought himself that the hilarious *bonhommie* of a prince of good fellows might almost be too contagious on such a grand occasion. Pasteur certainly seemed to have the monopoly of the conversation and charms of the Queen of Greece; but for an intimate *tête-à-tête*, which seemed as if it were to have no ending, commend me to the chat of the Queen of Denmark and Sir James Paget. Her Majesty seemed as if she would not part with the distinguished baronet. The clock hand moves round even at Copenhagen, and as I have to dine with the President of the Congress at six o'clock, I must reserve for another post a few more stray notes, leaving you to determine if they are likely to interest your readers.

Copenhagen, August 10th, 1884.

THE CHOLERA EPIDEMIC.

AT Toulon the cholera epidemic shows further signs of subsidence, for not only has the number of deaths been reduced to from one to two or three a day, but the fresh attacks which occur are of a much less severe character than they were. Much the same may be said as regards Marseilles, although there the mortality remains higher than at Toulon, and the disease still exhibits a tendency to recur in outbursts. Extension also continues to take place to neighbouring localities to which the inhabitants of infected places have fled, some of the more striking outbreaks having occurred at Cigean, in the Herault, and in villages in the Basses Alpes. The previous extensions to Arles and to Aix have, however, not been maintained to any serious extent, and this circumstance tends to show that the poison is less virulent than it has been, and gives hope of a general abatement of the disease in the South of France. Perhaps the most important event of the past week has been the obvious spread of the epidemic into Northern Italy, several fresh places in the provinces of Turin, Parma, and of Genoa being now admittedly infected, and this notwithstanding the quarantine measures which have been so stringently enforced. So far, however, there has been no tendency to any rapid diffusion of the infection, and in view of the sanitary precautions which are being taken, it is more than probable that no real epidemic will be experienced in Italy this autumn. Except as regards infantile diarrhœa, which is still prevalent, the sanitary condition of Paris remains satisfactory. The returns for the week ending the 9th inst. show no case of cholera, and the druggists in some quarters testify to an unusual absence of bowel complaints, owing to the general abstinence from unripe or indigestible fruits. Paris is, nevertheless, undergoing a process of depletion; the departures of visitors being 24,873, against 21,544 arrivals. Liverpool has again had to adopt stringent measures of inspection, isolation, and disinfection, owing to the arrival of a vessel which had taken on board some soiled linen at Marseilles, and which had in consequence suffered from cholera. No active cases of the disease have been imported, but patients suffering from debility and other symptoms following on the secondary fever have had to be placed under careful surveillance and treatment. The measures which have been adopted by Dr. Stopford Taylor and the Sanitary Committee of the Port Authority have amply sufficed to deal with the emergency. Elsewhere occasional rumours of cholera have occurred in this country, but none of them have been of a character to cause anxiety as regards extension, and it cannot be too widely understood that a fatal attack of choleraic diarrhœa at this hot season of the year may be, and often is, accompanied by symptoms which it is difficult to distinguish from those of true cholera; but still the disease has not the power of diffusion which attaches to the imported Asiatic affection.

THE REPORT OF THE FRENCH COMMISSION.

At the meeting of the Paris Academy of Medicine on Aug. 5th, M. Strauss presented on behalf of M. Roux and himself a report upon their investigations on the cholera at Toulon, researches which were practically a continuation of those carried on by them in Egypt in conjunction with the late M. Thuillier and M. Nocard. They assert that they invariably found the same lesions as those observed in Egypt, where search was made for a special microbe in the intestine by means of methyl-blue staining of sections of specimens preserved in alcohol. Various kinds of micro-organisms were found in the mucous membrane, ducts of the tubular glands, the villi, and in places in the submucous tissue, the majority being bacilli of varied shape and size. At Toulon MM. Strauss and Roux again sought for a specific organism like that found by Koch, and their observations confirmed what they had met with in Egypt. Micro-organisms were found in many cases, especially those where the disease was prolonged, but in the most rapid cases these organisms are much less numerous, and in the very acute cases it was impossible to detect them, even by the method adopted by Koch, whose statements on the point are referred to. The French observers go on to state that the characteristic choleraic stools are found to contain many kinds of micro-organisms, and in many cases but few that are comma-shaped. The intestinal contents obtained post mortem exhibit the same variety in bacteria, without any predominance of comma bacilli. In one extremely rapid case examined in the presence of Dr. Koch, the small intestine was coated with a layer of mucus which contained a pure culture of comma bacilli. These facts lead MM. Strauss and Roux to assign an important part in cholera to the comma-shaped organism; yet there are cases where the variety of intestinal organisms is so great that no special form preponderates. In such cases Koch resorts to cultivation to detect the comma bacillus, and the report goes on to describe the method of culture, the development of the bacillus, and the conditions of its existence. The reporters believe that until cholera can be transmitted by the administration of a pure culture of this organism, its specific character will be incapable of proof. Koch relies largely on the observation that the comma bacillus is not found in the healthy intestine or in any disease but cholera, so that if it could once be found apart from cholera, doubt would be thrown on its specific character. Dr. Maddore (of Tendres) photographed a comma-shaped microbe met with in a reservoir; M. Malassez showed the commission some comma-shaped bacilli in dysenteric stools, and M. Strauss has detected similar organisms in leucorrhœal discharge, and in the uterine secretion of a case of epithelioma of the cervix. The Commissioners further point out that if the comma bacillus be the cause of cholera, its limitation to the intestine and, in the more acute cases, its non-invasion of the mucous membrane, must necessitate the notion that it is capable of secreting a soluble ferment or poison, the absorption of which produces the symptoms of cholera. Attempts must therefore be made to extract from pure cultures of the bacillus a soluble poison having this action upon animals. It would also be of interest to ascertain whether in well-marked cases of cholera nostras the comma microbe is

Digitized by Google

present. The particulate bodies resembling organisms first detected in the blood by the Commission in Egypt have again been met with in the Toulon cases, and are believed to be due to a special change in hæmoglobin.

FOREIGN QUARANTINE REGULATIONS.

NOTIFICATIONS to the following effect have been given in the *London Gazette* of August 8th and 12th:—

A service of medical superintendence has been organised at several of the French railway stations to oblige travellers who may be found to be ill to break their journey.

All ships arriving at St. Petersburg from suspected ports are to be subjected to twenty-four hours' quarantine, even though they be provided with a clean bill of health.

At Algiers ten days' quarantine is imposed on all vessels arriving from Marseilles and Toulon, and five days' quarantine on vessels from other infected ports.

Eleven days' quarantine is imposed at Athens on vessels arriving from the Italian peninsula, and five days' observation on arrivals from French Atlantic ports.

Arrivals from Tunis at Austrian ports are subjected to a quarantine of observation of ten days if there has been no sickness during the voyage, and of twenty days if sickness has occurred.

At Madrid arrivals from Italian ports are placed on the same footing as those from French ports, and must consequently perform quarantine at a lazaret port of seven, ten, or fifteen days, according to circumstances.

THE HEALTH EXHIBITION.

THE SANITARY AND INSANITARY HOUSES.

THE whole object of an exhibition is to teach by the eye, which as a gateway of knowledge is allowed by all to be more effectual than the ear. The idea, therefore, of placing side by side two houses, of the ordinary type, one shewing the common sanitary defects, and the other showing how these common defects may be best avoided, and asking the British public to "look on this picture and on that," was, to say the least, a happy one. The idea has been well carried out by Messrs. Rogers Field, Ernest Turner, Corfield, and Douglas Galton; and the Executive Council of the Health Exhibition are to be congratulated on the completion of this important addition to their great show. The work has been some time on hand, as there arose sundry difficulties before an exhibit so full of detail could be completed. Now, however, that the work is done, all will agree that it has been worth waiting for, and it is to be hoped that in the ten weeks or so which will elapse before the close of the Exhibition it will be seen by a large number of the class of artisans upon whom we rely for the construction of our dwellings.

Visitors are conducted first through the insanitary house, where the lesson conveyed is "How not to do it." The dustbin is too big and inaccessible; there is a pipe drain under the basement cemented only at the top. The sinks and closets are without light and air; the apparatus used is of the common bad type; the soil pipes are unventilated; the pan-closets have no safes; bell-traps and D-traps abound; the drinking water is being contaminated by air charged with the products of the decomposition of excrement; the lavatory basin is a duct for sewer gas, as is also the waste-pipe and overflow-pipe of the bath. The water cistern is poked away under the roof, the damp is rising on the walls, the papers are arsenical, and the ventilation is very defective. This "shocking example" is not overdone. The defects shown come daily under the eye of medical men, and as we walked through this dwelling, visions of sore-throat, headache, malaise, typhoid, diarrhœa, and puerperal fever filled the mind.

Having made the circuit of the unhealthy house from basement to top storey, the visitor passes along a passage into the sanitary house, and he is at once confronted with properly ventilated gas-pipes, tube ventilators for the admission of fresh air, and at the top a light and airy cistern-room, in which the cisterns (for there are two, one for drinking water and the other for flushing water, &c.) are easily got at and cleaned. The cork flooring to the bath-room, the window latches, the deep bead at the bottom of some of the windows so that air may find its way into the house between the sashes, are all details sure to strike anyone with an eye for wholesomeness.

The waterclosets are against outside walls, the closets are properly fixed, the overflow pipes open into the air, there are separate waste-preventing cisterns for the waterclosets, and the soil-pipes are ventilated; all this has been accomplished easily, and in spite of the fact that the two houses are of almost identical area and pattern. Then, again, we find a bath of excellent pattern, incandescent electric light, clean and beautiful sinks, parquet floors, ventilating stoves, an impermeable iron-pipe beneath the house, the waste-pipes ending over gulleys, and a proper disconnecting chamber to cut off the house from the street sewer. The front area is lined with white tiles, and the dustbin is replaced by a galvanised iron box. Finally, the visitor emerges through the front area much impressed by the contrast.

There were certainly many plumbers and artisans inspecting these houses on Tuesday, and we can only hope that every plumber in Great Britain may find an opportunity of so doing.

INTERNATIONAL HEALTH EXHIBITION LIBRARY.

The library which has lately been opened in connexion with the Exhibition numbers upwards of 8000 volumes, and contains valuable collections of census and cholera reports, reports of English and foreign sanitary commissions, of medical officers of health, and of vital statistics; also Transactions of Societies and journals relating to health; in the latter may be mentioned a complete series of volumes of THE LANCET from the commencement to the current year (1823-1883), 121 volumes. The medical works on health are very complete, and such subjects as food, dress, dwelling-houses, ambulances, &c., are numerously represented. The collection of English and foreign guide-books, and medical and popular treatises relating to health resorts at home and abroad, are numerous. The Italian Government deserve special mention for their complete and valuable set of sanitary and educational reports. The Executive Council may be congratulated in having formed, under the direction of a sub-committee, such a valuable library, which, we trust, may be increased by the forthcoming Exhibitions. Mr. Carl A. Fhimm, the librarian, is to be complimented on having arranged, classified, and catalogued the library in a remarkably short space of time. The catalogue, which is published, is printed in double columns, and consists of 138 octavo pages.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in the Kingsclere Rural District, by Dr. BLAXALL.[1]—This outbreak, which affected five different localities in the Kingsclere rural district, exhibited in its early history the difficulty so often met with as to what constitutes the origin of this disease. "Mumps" had for some time past been very prevalent, but some of the school children who had been affected had also suffered from symptoms indicative of diphtheritic paralysis, such as regurgitation of fluids on drinking, altered voice, and impaired vision; throat affections in different forms had been prevalent, and amongst these a certain number had been scarlatinal in character. Following on this sequence of cases, diphtheria as such was first recognised at Ashford Hill in July, 1883, when a child was affected who was in attendance at a school in Ashford. But inquiry at the school disclosed the fact that there had previously been a number of absentees from school owing to "mumps and sore-throat"; and after their first attack others followed which evidently derived their infection from the same source, fifteen of the seventeen primary attacks being attendants at

[1] To be purchased of Knight and Co., 90, Fleet-street; Shaw and Sons, Fetter-lane; Hadden, Best, and Co., West Harding-street; and P. S. King and Son, King-street, Westminster.

Digitized by Google

the Ashford school. Other localised attacks took place at Headley Common and at East Woodhay, the attacks at the latter place being preceded by a number of cases of sore-throat in the school and neighbourhood. The true nature of these attacks may be gathered from the facts that in some of them the parents had noted that their children's throats were white inside, that in others the voice and vision were affected, and that the death certificate in one instance includes the obscure term "croup." In all, five different localities were effected, the number of cases was forty-seven, the different families attacked numbered twenty-four, and eleven deaths took place. As regards the origin of the affection, geological circumstances go for nothing. The localities in question lie mainly on the London clay and the Lower Bagshot beds, some infected dwellings standing at high elevations, others on the slopes of the hills, others again on a level with neighbouring streams. The ordinary village nuisances were by no means absent, but nothing could be pointed out capable of being regarded as a clear cause of diphtheria. Food supplies could with some confidence be excluded as a cause, and it was found impossible to detect any community of condition or circumstance peculiar to the homes or the home life of those who were affected which was not equally applicable to those who escaped. As regards Ashford Hill, either a child or one of the teachers who was temporarily absent owing to certain throat symptoms appears to have been the exciting cause of the disease which diffused itself among the school children; but how these first attacks originated is not made out. The subsequent spread of the disease was facilitated by intercommunication, especially amongst members of the same family, by attendance in the harvest fields, or at places of public amusement. The inquiry appears to have been worked out by Dr. Blaxall with a care that leaves nothing to be desired, and yet, as in so many other cases, no fresh light is thrown on the origin of the disease. The principal difficulty, here as elsewhere, seems to lie in the fact that early cases of throat affection which are not of such a nature as to excite suspicion are capable of diffusing themselves somewhat widely, until at last obvious diphtheria is being spread, and then the remedy comes too late. It will only be by a much more intelligent appreciation on the part of the public of the fact that apparently simple cases of sore-throat may lead to fatal outbreaks of disease that the remedy against diffusion can be hoped for. In the absence of strict measures of isolation for these cases, the major disease is often produced, and then no means of isolation are available for the comparatively large number of persons who have sickened.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Billericay (*Rural*).—This rural district had a death-rate of 21·0 per 1000 in 1883, and the excess beyond that which should obtain in such a district was to a notable degree due to zymotic disease. Thus diphtheria was somewhat widely diffused through the district, causing seventeen deaths; and this probably indicates a very large amount of throat affection, for, as Dr. Carter suggests, it is hardly probable that more than one case in fifteen terminated fatally. Dr. Carter is inclined to think that faulty sanitary conditions do not produce diphtheria any more than they lead to small-pox; but that, on the contrary, the disease is always due to infection, the poison invariably breeding true. There is much experience which is opposed to this view, and there are few districts so well administered that it becomes possible to exclude faulty sanitary circumstances as a cause. Once produced, we fully concur with Dr. Carter that diphtheria is intensely infectious by means of personal communication, and that at times certain geological and sanitary conditions favour its retention in a stage in which it is potent for harm.

Helmsley (*Rural*).—Scarlet fever, which caused forty-five deaths in this district, was the only infectious disease which became diffused in 1883, diphtheria and enteric fever being remarkable by their entire absence. Apparently no means of isolation have been provided by the sanitary authority. A remarkable outbreak of diarrhœa occurred at Hawnby, where it mainly attacked school children, and the details were communicated to Dr. Ballard in connexion with his general inquiry into the causes of that disease. Although the district is one where sanitary improvements are still needed, yet according to Dr. Bruce Low much has been done, and the death-rate for the year was only 14·6 per 1000 living, notwithstanding the epidemic of scarlet fever. On the whole he believes that at a minimum expenditure there has been a fair return of health to the district, and whilst he admits that there is ground for satisfaction, yet he impresses on his authority the need for further action and the danger of falling into a false sense of security.

Glanford Brigg (*Rural*).—This district has an estimated population of 29,041; the death-rate during 1883 was 19 per 1000, and the birth-rate 36 per 1000. The infantile death-rate is high, amounting as it does to 21·5 per 100 registered births in the villages where ironworks are carried out. In the rest of the district the rate is only 11, which is about the usual rate in normal agricultural villages. Scarlet fever was somewhat prevalent, causing 23 deaths and necessitating the closure of schools. Typhoid fever occurred in ten different localities, and notably at South Ferriby, where it was apparently caused by the use of contaminated drinking-water. Measures have now been taken to remedy this serious defect. An exceptional mortality is reported by Mr. Moxon as having occurred from puerperal fever, no fewer than twenty women having died shortly after childbirth. After a time some of the medical practitioners altogether abstained from midwifery practice, and then the disease ceased. During the three months preceding the issue of the report no fresh case had occurred. The account of sanitary work carried out shows that the conditions under which the people are living are steadily undergoing improvement.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 9th inst. 5132 births and 3670 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had been 24·9 and 23·3 per 1000 in the two preceding weeks, further declined last week to 21·9. During the first six weeks of the current quarter the death-rate in these towns averaged 22·6 per 1000, against 19·6 and 20·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 14·8 in Bristol, 15·7 in Brighton, and 16·7 in Bradford. The rates in the other towns ranged upwards to 27·3 in Halifax, 27·5 in Leicester, 29·0 in Preston, and 30·2 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which in the two preceding weeks had been 1246 and 1035, further declined last week to 911; these included 585 from diarrhœa, 92 from measles, 75 from whooping-cough, 70 from scarlet fever, 45 from "fever" (principally enteric), 22 from diphtheria, and 22 from small-pox. These diseases caused the lowest death-rates in Huddersfield and Plymouth, and the highest in Liverpool, Bolton, and Salford. The highest death-rates from diarrhœa were recorded in Portsmouth, Bolton, Leicester, and Salford; from measles in Wolverhampton and Halifax; from whooping-cough in Halifax; and from scarlet fever in Cardiff, Sheffield, and Wolverhampton. The 22 deaths from diphtheria in the twenty-eight towns included 18 in London. Small-pox caused 16 deaths in London (exclusive of 3 metropolitan cases registered outside Registration London), 2 in Liverpool, 2 in Sunderland, 1 in Hull, and 1 in Cardiff. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the four preceding weeks from 1368 to 892, further fell to 810 on Saturday last; the cases admitted, however, which had fallen in the seven previous weeks from 354 to 66, rose to 110 last week. The Highgate Small-pox Hospital contained 45 patients on Saturday last, 6 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 159 and 198 in the two preceding weeks, declined last week to 187, and slightly exceeded the corrected average. The causes of 83, or 2·3 per cent., of the 3670 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Nottingham, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Sunderland, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the two preceding weeks had been 23·3 and 20·6 per 1000, was 20·7 in the week ending the 9th inst.; it was 1·2 below the mean rate during the same week in the

Digitized by Google

twenty-eight large English towns. The rates last week in the Scotch towns last week ranged from 11·6 and 15·7 in Perth and Greenock, to 23·2 in Paisley and 24·3 in Glasgow. The 500 deaths in the eight towns included 51 which were referred to diarrhœal diseases, 31 to whooping-cough, 14 to scarlet fever, 7 to diphtheria, 6 to measles, 5 to "fever," and not one to small-pox; in all, 114 deaths resulted from these principal zymotic diseases, against 85 and 95 in the two preceding weeks. These 114 deaths were equal to an annual rate of 4·7 per 1000, which was 0·7 below the average rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœal diseases, which in the three previous weeks had declined from 57 to 40, rose again last week to 51, but very slightly exceeded the number in the corresponding week of last year; they included 23 in Glasgow, 13 in Dundee, and 6 in Paisley. The death-rate from diarrhœa in the Scotch towns last week did not exceed 2·1 per 1000, whereas it averaged 3·5 in the large English towns. The 31 deaths from whooping-cough showed a further increase upon those returned in recent weeks, and included 20 in Glasgow and 4 in Edinburgh. Of the 14 fatal cases of scarlet fever, 13 occurred in Glasgow, where 3 of the 7 deaths from diphtheria were also recorded. The 6 fatal cases of measles showed a decline of 10 from the high number in the previous weeks, while those of "fever" showed a slight increase upon recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns, which had been 89 and 66 in the two previous weeks, were last week 65, and exceeded by 11 the number returned in the corresponding week of last year. The causes of 72, or 14·4 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 19·3 and 23·0 per 1000 in the two preceding weeks, declined to 22·4 in the week ending the 9th inst. During the first six weeks of the current quarter the death-rate in the city averaged 21·7 per 1000, the rate during the same period being equal to 23·3 in London and 17·2 in Edinburgh. The 151 deaths last week in Dublin were within four of the number in the previous week, and included 23 which were referred to the principal zymotic diseases, against 16 and 22 in the two preceding weeks; of these, 8 resulted from diarrhœal diseases, 6 from scarlet fever, 6 from "fever" (typhus, enteric, or simple), 3 from whooping-cough, and not one either from small-pox, measles, or diphtheria. These 23 deaths were equal to an annual rate of 3·4 per 1000, the rate from the same diseases being 4·9 in London and 2·1 in Edinburgh. The fatal cases of diarrhœa showed a decline of 3 from the number in the previous week; the 6 deaths referred to scarlet fever showed a slight increase upon recent weekly numbers. The 6 fatal cases of "fever" corresponded with the number in the preceding week. Three inquest cases and 2 deaths from violence were registered in the city during last week; and 57 deaths occurred in public institutions. The deaths of infants showed a considerable decline, while those of elderly persons exceeded the numbers in recent weeks. The causes of 21, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY.—Fleet Surgeon Donald MacIver, M.D., has been placed on the retired list.

The following appointments have been made:—Staff-Surgeon W. H. Stewart, to the *Clyde*; Staff-Surgeon A. G. Delmege, to the *St. Vincent*; Staff-Surgeon H. T. Cox, to the *Canada*; Staff-Surgeon H. E. F. Cross, to the *Cambridge*; Surgeon Jeremiah Sugrue, M.D., to the *Watchful*; Surgeon A. G. P. Gibbs, to Haslar Hospital; Surgeon D. S. Gunn, to the *Canada*.

ARTILLERY VOLUNTEERS.—3rd Lancashire: Surgeon Matthew J. Rae, M.D., resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.

ENGINEER VOLUNTEERS.—2nd Tower Hamlets (East London): William Bull, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Hertfordshire: Surgeon George Etin, M.D., resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.—1st Shropshire: Surgeon Thomas Greville Thursfield, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement. Acting-Surgeon William Thursfield, M.D., to be Surgeon.

Correspondence.

"Audi alteram partem."

THE LONDON UNIVERSITY PRELIMINARY SCIENTIFIC EXAMINATION.

To the Editor of THE LANCET.

SIR,—In the interest of many deserving students, whose honest labour is being cruelly wasted, and whose prospects in life are being seriously injured, I ask you to publish the accompanying papers in physics recently set at the Preliminary Scientific Examination of the University of London.

INTERMEDIATE SCIENCE AND PRELIMINARY SCIENTIFIC (M.B.) PASS EXAMINATIONS, 1884.

Experimental Physics.

Examiners: Professor G. Carey Foster, B.A., F.R.S.; and Professor A. W. Reinold, M.A., F.R.S.

Tuesday, July 22nd. Morning—10 to 1.

1. A railway train of 300 tons is running at 45 miles an hour: find its energy of motion in foot-tons. Also, if the engine while getting up the speed of the train does work on it at an average rate of 100 horse power, show how long it will take to get up the speed of 45 miles an hour. [Take $g=32$ (feet, seconds); 1 horse power = 33,000 foot-pounds per minute.]

2. A cage weighing 240 pounds is lowered with uniform acceleration down the vertical shaft of a coalpit, the velocity changing from 100 to 200 feet per second while the cage descends 600 feet. Determine the force exerted by the cage on the rope by which it is lowered.

3. How can the amount of work done against external pressure during change of volume be expressed numerically? One gram of air is heated under constant pressure from 0° to 10°C.: determine the work, either in *ergs* or in *centimetre-grams*, due to the expansion. [Coefficient of expansion of air $=\frac{1}{273}$. Volume of 1 gram of air at 0°, under pressure of 1 million dynes per square centimetre = 783·8 cubic centimetres. Or, 1 cubic centimetre air at 0° under pressure of 76 c.m. mercury = 0·001293 gram; 1 cubic centimetre mercury at 0° = 13·596 grams; $g=981$ (centim., seconds).]

4. Explain why the rise of temperature due to compression and the fall of temperature due to rarefaction in a sound-wave both tend to raise the velocity of propagation of the wave.

5. How does the pitch of the note sounded by an open organ-pipe depend on the length of the pipe and the velocity of sound in air? Show how the note is affected by changes of temperature.

6. Describe some method by which the expansion of water has been studied. If δ be the expansion of water between 4° and 0°C. and Δ its expansion between 4° and t°, show what is the density of water at t° referred to water at 0°. 7. How does the boiling point of a liquid depend on the pressure to which it is exposed? Describe Regnault's method, founded on the variation of boiling-point referred to, of determining the maximum pressure of vapours at various temperatures. 8. Two air-thermoscopes, one with a clear glass bulb, the other with a bulb covered with gold-leaf, are placed (a) one after another at the principal focus of a convex lens presented to the sun; (b) at equal distances in front of a common fire. In both cases the thermoscopes are found to be unequally heated. How do they differ, and why?

Afternoon—3 to 6.

1. Describe the principle of measurement employed in the torsion-balance. A magnet suspended by a fine vertical wire hangs in the magnetic meridian when the wire is untwisted. If on turning the upper end of the wire half round the magnet is deflected through 30° from the meridian, show how much the upper end of the wire must be turned in order to deflect the magnet 45° or 60° respectively.

2. If a metal ball, hung by a dry silk thread, be made to touch the inside of an electrified metal jar and then carried to an electroscope, the electroscope is not affected; but if the electroscope is connected with the inside of the jar by a wire, it receives a charge. Account for the difference between the two results.

3. *A*, *B*, and *C* are three Leyden jars, equal in all respects. *A* is charged, made to share its charge with *B*, and afterwards to share the remainder with *C*, both *B* and *C* being previously without charge. The three jars are now separately discharged. Compare the quantity of heat resulting from each discharge with what would have been produced by the discharge of *A* before any sharing of its charge.

4. Ten galvanic cells, each of internal resistance 2 and electro-motive force 1·8, are connected (*a*) in a single series; (*b*) in two series of five each, the like ends of the two series being joined together. If the terminals are in each case connected by a wire of resistance 10, show what is the strength of the current in the wire in each case, and compare the rates of consumption of zinc.

5. Two wires whose electrical resistances are as 3 to 5 are connected (*a*) in series, or end to end; (*b*) abreast, or "in multiple arc"; and a current of the same total strength is sent through each combination. Compare the quantities of heat produced per second in each wire in the two cases.

6. When a thermo-electric pile is introduced into the circuit of a

Digitized by Google

battery, the strength of the current is reduced rather more than by the introduction of a simple wire of the same resistance as the pile. Account for this effect.

7. A gold fish globe of six inches' radius is filled with water. Determine the apparent position of a point inside the globe, 4 inches from its surface, when seen by an eye outside looking along a radius of the globe.

8. Trace the changes in the position and size of the virtual image formed by a concave lens when the object moves from an infinite distance up to the lens. Explain how the image is formed by the concave eye-piece of an opera-glass.

Besides being extraordinarily difficult and pedantically framed, they deal with departments of natural philosophy far removed from the requirements of future medical men. They might be fit for an advanced class of civil, mechanical, or electrical engineers, devoting all their time and energies to mathematical physics; for young men still under age, who have to get up zoology, botany, and chemistry simultaneously, they are simply disgraceful. It is, therefore, not surprising that, as Dr. Bristowe, himself a distinguished student of the University, has shown, of a hundred who begin this career only ten succeed in completing it. It is also unfortunately obvious that where such recondite and uncommon questions are asked, there must be, even with the greatest care, an advantage given unintentionally to pupils attending the classes of examiners who are themselves teachers.

I am, Sir, yours, &c.,

WILLIAM H. STONE,
August 4th, 1884. Censor, Royal College of Physicians.

HEALING OF WOUNDS IN THE SOUDAN.

To the Editor of THE LANCET.

SIR,—I have had under my care at the Egyptian Military Hospital, Suakin, for fifty-seven days, three men whose right hands were amputated by order of Osman Digma forty-five days before they came under my charge. During these forty-five days they were kept prisoners in chains at Osman's camp at Tamanieb, their wounds being quite unattended to, they themselves having torn a piece off their scanty cloth to wrap round the stumps. When freed, they made their way direct to Suakin and appeared at the hospital for treatment.

As may be imagined, the dressing was in a rather filthy state, but I was surprised to find that active and healthy granulation was going on, with small discharge and no pain, the bones being quite covered by granulations, the stumps large, and healthy ulcers with small healing edges, which after a few days' dressing in hospital grew over the granulations with great vigour. At present the stumps are perfectly rounded, and with a very slight scar where the last of the dermis covered the granulations.

It may interest some of your readers to know how Osman performs his amputations. The right hand of the unfortunate "friendly" was grasped by one man, whilst another tied round the forearm a rope so tightly as to stop the circulation. This rope was dragged upon in one direction, the hand in the opposite. A third operator with one of the ordinary Soudanese curved knives made a circular incision round the wrist over the radio-carpal joint, and so between dragging and cutting the hand was separated from the arm. The method of preventing hæmorrhage was as follows. Before the cord on the arm was loosed, a pot of tallow was placed over a charcoal fire, the men operated on squatting in the usual Eastern fashion till the tallow boiled, then one by one their stumps were thrust into the boiling tallow and kept there till danger of hæmorrhage was supposed to be over. Afterwards they were kept in irons till the day before they appeared in Suakin.

I cite other two cases which have come under my care here.

1. An Abyssinian boy, sixteen years of age, who was in General Baker's battle of Teb, was retreating with the other Abyssinians engaged there, when he was struck by a spear over the superior border of and close to the right scapula, the spear penetrating in a downward direction, and the point making its exit below the clavicle at the junction of the middle and outer third. After receiving the wound the boy assisted in killing the man who struck him, and ran seven miles—i.e., to the harbour of Tokar; he was then shipped to Suakin. The spear measured four inches wide at its tip to 2in. at its base, and from 1in. to ¾in. thick in its central rib. No important blood-vessels were injured, no nerve cords were much hurt, and not a bad symptom appeared in the wound, which was quite healed in six weeks. For two or three weeks afterwards he had slight pain in the course of the musculo-spiral nerve, which quite disappeared.

2. An Abyssinian was shot at the battle of Tamar, the ball passing through the upper part of his thigh close behind the femur, then through the scrotum without injuring the testicles or cords. He was walking about in hospital in the three weeks.

I believe all these cases are examples of the rapid and certain healing of wounds so often seen here in natives of the Soudan and Abyssinia. Many other cases have come under my notice. In no cases have I seen suppuration, except in those where no precautions have been taken to keep the wounds clean, and the Listerian antiseptic system is not carried out by me. Abstinence from alcoholic liquors and simple feeding might be said to explain the sure healing of the wounds of the Soudanese, but not of the Abyssinians, who drink whenever opportunity occurs, and eat as much butchers' meat as they can afford, and on special occasions without cooking it. The dressings used in all the cases cited were simply carbolic water, lint, and gutta-percha tissue; over that a compress of cotton cloth and a bandage.

I am, Sir, yours truly,

ALEX. GALBRAITH, M.B.,
Suakin, July 26th, 1884. Surgeon-Major, E.A.

THE ANCOATS MURDER CASE.

To the Editor of THE LANCET.

SIR,—Since the issue of last week's LANCET, in which you make some comments in a leading article on what has been called the Ancoats murder, my attention has been directed to certain facts connected with the case. It appears that the accused man, Donnelly, was, eighteen months ago, a patient of mine at the Hospital for Epilepsy and Paralysis, suffering from a severe form of epilepsy, accompanied with serious attacks of temporary mental derangement. At that time the patient stated that under the influence of his complaint he had frequently committed assaults and other crimes, for which he had been arrested, and even wrongly punished by imprisonment. While in the hospital, on several occasions he performed acts of violence obviously under insane impulses, and of which he was afterwards totally unconscious. He was finally discharged unrelieved, and considered as incurable. Although it was obvious at the time that this individual should have been placed under some kind of restraint, the law does not recognise the necessity of interfering with the liberty of the subject under such circumstances. Accordingly, after years of minor misdemeanours against society, it is only after murder and homicidal assault have been perpetrated—a sister having been killed and a mother mutilated—that the actor in all these offences has received the official attention which his case has so long merited. Furthermore, this unfortunate wretch, having at last been arraigned before a jury of his countrymen, has been compelled to undergo the mental torture not only of being tried for the most awful crime of which a man can be accused, but of being pronounced guilty of wilful murder, and actually sentenced to death as a malefactor of the most brutal and unnatural type. That this legal judgment has since been partially remitted will be little consolation to the accused or his family, after all the agonies of mind they must have endured.

I quite agree with your editorial remarks that the essential facts connected with an important criminal inquiry should be elicited at the trial, and not after the accused has been condemned to death as a murderer, and my object in addressing this letter to you is to express the opinion that in this case the disastrous uncertainty might have been entirely avoided had the matter been properly investigated at that time. There seems, in short, to have been an oversight on the part of the defence in failing to ascertain the ordinary circumstances in behalf of the prisoner. He had been a patient of Dr. Dreschfeld of Manchester, who doubtless could have testified to his condition. He was under my own observation for some months. I possess full notes of his case, and could have strongly advocated his irresponsibility. Although the authorities were duly informed that the accused had been in infirmary at least two public hospitals, no efforts were made to utilise this evidence in his favour, and no medical man was called upon to prove his mental condition. These, in short, who could have placed the whole matter in such a light as would have convinced any jury

Digitized by Google

of the innocence of the prisoner were in no way consulted. All that was thought necessary in this respect was to demand the attendance of a nurse as a witness, who was called upon to answer questions of opinion which might have severely taxed the acumen of the most talented psychologist. Even this was the result of chance, and due to the matron of one hospital, who, accidentally seeing the case in the newspapers, voluntarily communicated with the police, informing them of our experience of Donnelly's habits.

Without going further into this case than pointing out the absence of obtainable medical advice, does it not appear that, owing to its omission, the defence was very imperfectly conducted, and that there was great negligence in failing to elicit what would have been of vital importance to the accused? No one acquainted with the mental condition of the prisoner, and reading the public reports of his trial, could have the slightest doubt of his irresponsibility in the crime he committed, and had the sentence of the law been carried into effect, it would have been little else than an official murder. Had this been properly represented to the jury at the trial, there can be no question that their verdict would have been different. It is scarcely justice that in this momentous problem of trying a man for his life important considerations should be withheld, and that, as a result, a man should be denounced as a murderer, condemned to death, and only saved from execution by a tardy and precarious after-investigation. As it is, the public have a right to be informed whether this individual is for the future to be considered and treated as a lunatic, and consequently as an innocent man, or whether he is to undergo penal servitude for life as a malefactor.

I am, Sir, yours faithfully,

Queen Anne-street, Aug. 12th, 1884. A. HUGHES BENNETT.

LIVERPOOL.

(From our own Correspondent.)

THE HOLIDAY SEASON.

This annual holiday, so grateful to all who dwell in large cities, has already been enjoyed by a large number of citizens, including both practitioners and patients. Liverpool possesses admirable facilities for a pleasant holiday trip. Within a short railway journey are the English lake and Welsh mountain districts. Seven hours' pleasant journey by rail brings visitors to Glasgow or Edinburgh, whence all that is attractive in Scotland may be easily reached. Those who prefer the sea have an *embarrass de richesse* in the many sea trips which are offered daily to the Welsh and Irish coasts, the Isle of Man, and the west coasts of Cumberland and Scotland. A very enjoyable trip is from Liverpool to Leith round the north of Scotland, calling at Oban, Stornoway, Stromness, and other points of attraction, occupying five days. Every care is taken to secure the comfort of the passengers, who thus have the opportunity of seeing the most picturesque parts of Scotland under most favourable auspices.

KEEPING OUT THE CHOLERA.

Considering the constant communication which is maintained between Liverpool and the different French seaports, it is gratifying to state that no case of cholera (other than ordinary cases of English cholera) has yet been reported. Every precaution is being taken to prevent infection being imported, and, under the direction of the medical officer of health, the disinfection of waterclosets in crowded streets and courts is being diligently carried out. The *Tarapaca*, a Liverpool ship, was placed in quarantine, having called at Marseilles, and lost one of her hands from what was evidently a case of cholera. It was reported in the local papers that proceedings had been taken against the sanitary authorities by the owners of the vessel, but this has been contradicted by the latter, who were only too willing to afford every assistance.

THE HEAT.

Although the thermometer has not attained here the height recorded in London, it has been higher than has been known for some years, considerably exceeding 80° in the shade. For some days past there have been appearances indicating a coming storm, and, at the present time, it is much cooler.

THE RECENT CASE OF GOOD *v.* WHITTLE.

Actions against medical men have a tendency, like some diseases, to appear from time to time in an epidemic form, and the recent cases in which Mrs. Weldon was the plaintiff, the Bower and Keates case, and others, would show that the present year is witnessing a recurrence of this epidemic. The case of Good *v.* Whittle, which came to a close last Saturday, has happily ended, so far, in favour of the defendants, who will, however, it is feared, be subject to heavy costs. The verdict has been received with much satisfaction in professional circles, it being evident that they acted throughout in perfect good faith.

IRELAND.

(From our own Correspondent.)

QUEEN'S COLLEGES COMMISSION.

THE members of this Commission held a brief meeting on the 7th inst. Dr. Banks, Regius Professor of Medicine in the University of Dublin, was examined, and stated that his opinion of the standard of education both in Arts and Medicine in the Queen's Colleges was very high. He considered that the period of study for the profession of medicine was too short in this country, and believed that competitive examinations had done a great deal of harm. He objected to men without sufficient education entering the profession, and thought it a great pity that poor men should do so. The Commissioners on Monday last resumed that part of their inquiry relating to the medical schools in connexion with the Queen's Colleges, when Dr. Cruise and Messrs. W. J. Stoker and McArdle were examined.

MERCER'S HOSPITAL, DUBLIN.

Steps are being taken to have this institution—one of the oldest in Dublin, its existence dating back 150 years—enlarged by an addition fronting King-street. The projected building will comprise a new surgery, theatre, and pharmacy, with apartments for the house-surgeon, matron, and resident pupils; and it is also intended to provide a new waiting-room for extern patients. It is probable that a pay-ward will be established, as exists in most hospitals, and which it is expected will add to the funds of the institution. At present there is a debt due amounting to some £1800, which impedes the usefulness of the hospital, and it is to be hoped that the charitable will remove this debt and contribute liberally towards the expense of erecting the projected addition for a very deserving institution.

MIDDLETON WATER-SUPPLY AND SEWERAGE.

In consequence, as alleged, of the insanitary condition of this town, and the impure and insufficient supply of water, 108 cases of fever were treated in the hospital during the past ten months, with a mortality of 37. Dr. Foley, the medical officer, has drawn attention to the subject, and the Local Government Board have requested the guardians to take immediate steps to remedy the defects complained of.

PRECAUTIONS AGAINST CHOLERA.

Arrangements have now been completed for the berthing of infected vessels arriving in Dublin. Two large buoys have been placed at the North Wall Basin, where such vessels will be moored until removal from quarantine. The hospital ship has also been thoroughly fitted up for the reception of patients.

A BELFAST HOSPITAL SATURDAY.

A meeting of the special committee appointed to promote this movement was held recently at the Belfast Royal Hospital. The collection has been arranged to take place at upwards of one hundred stations on the last Saturday of this month, and it is to be hoped that the undertaking will be generously supported.

EXCISION OF THE LOWER JAW.

A few days ago Mr. Lambert H. Ormsby, of the Meath Hospital, Dublin, removed part of the lower jaw of a woman aged twenty-seven for a secondary return of ossifying sarcoma. A free incision was made, splitting the cheek from the commissure of the lip to the lobe of the ear, which laid bare the tumour, which was removed quite close to the temporo-

Digitized by Google

maxillary articulation. Considerable hæmorrhage followed from an unusual number of vessels, which were tied with chromocised gut. The case has since progressed favourably. Mr. Ormsby also operated on a woman aged thirty, who had undergone Symes' amputation of the foot six years previously; and although the parts rapidly healed, she had suffered the most excruciating pain in one defined spot at the end of the stump. An exploratory incision was made over the spot indicated, and a small piece of silver suture that had become embedded in the soft parts close to the bone was removed, and which had no doubt given rise to the pain for the past six years.

An election for a medical officer to Dundalk Workhouse took place last Monday, when Dr. Kearney was appointed at a salary of £100 per annum, with a fee of one guinea for each consultation as sanitary officer.

Dublin, Aug. 12th.

PARIS.

(From our own Correspondent.)

THE CHOLERA.

CHOLERA is still lurking in and about the neighbourhood of Toulon and Marseilles, but the admissions and deaths are steadily decreasing. The debate at the Academy of Medicine on the epidemic is being drawn out, and M. Fauvel, who is following it from his retreat in the country, has written to say that nothing as yet, either in the course of the malady or in the debate at the Academy, has transpired to induce him to alter his opinion as to its nature. From the discussions, however, it may be gathered that there are three opinions on the subject. The first, which is the most commonly entertained, is, that "cholera nostras," or, as it is also termed, sporadic or simple cholera, is an "individual" malady—that is, it strikes only certain individuals; it is non-contagious, and very different from Asiatic or Indian cholera. The second opinion is that both the maladies are one and the same, differing only in degree. The third is that maintained by M. Fauvel, and perhaps a few others, to the effect that the malady reigning at Toulon and Marseilles is neither the one nor the other, but that the present epidemic was brought about by special local conditions, and that it must die out without extending much farther, as it is essentially non-contagious, and consequently untransportable. Dr. Ernest Besnier, well known for his writings on epidemiology, made a very important communication in response to M. Jules Guérin and other orators at the Academy on the subject of cholera, and in expressing his surprise at the slow progress that is being made in the science of epidemiology, availed himself of the opportunity of proposing the creation of a chair of Epidemiology in all the medical faculties of the French Republic.

A NEARER APPROACH.

A propos of epidemiology and public hygiene, Dr. Linville has proposed at the Chamber of Deputies, a *projet de loi* tending to place under the same direction the different offices of public salubrity, which are just now dispersed among the various Ministers of State, subject to the inconvenience of individuals and the delay of public business.

PRIZES FOR WORKS ON TEMPERANCE.

The Temperance Society of Paris offers a prize of 2000 francs for competition this year for works relating to temperance and to spirituous liquors, in reference either to their composition or to their action on the economy. While no special subject is proposed, the Society would draw particular attention to the following subjects:—"Hereditary Alcoholism," "Measures which should be taken concerning Habitual Drunkards." The money will be divided among the successful candidates. The treatises, which may be printed or written, are to be forwarded to the General Secretary of the Society, 6, Rue de Mulhouse, Paris, before January 1st, 1885.

DEATH OF BARON THÉNARD.

Baron Thénard, member of the Academy of Medicine and of the celebrated chemist of the same name, died on the 7th inst. at his residence in the Château of [illegible] from the effects of [illegible] the Section of Rural Economy. The scientific works of Baron Thénard are well known to chemists and agronomists. It was this distinguished chemist who first succeeded in liquefying phosphoretted hydrogen, which renders spontaneously inflammable another gaseous substance similarly composed. It is this substance which forms the basis of the ignis fatuus observed in marshy grounds and cemeteries. Baron Thénard devoted a great deal of his time and attention to the phylloxera, and was member of the commission instituted in France in view of remedying the evil caused to the vineyards in this country.

Dr. Lannelongue has been appointed Professor of Surgical Pathology at the Paris Faculty of Medicine, in the room of Dr. Le Fort, transferred to the Chair of Clinical Surgery.

August 13th.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Thursday, the 7th inst. the Canal Boats Act Amendment Bill was read a third time and passed. On Friday, the 8th, the Criminal Lunatics Bill was read a third time and passed.

On Tuesday, the Disused Burial-grounds Bill, the object of which is to make it illegal to erect any building upon such grounds except those connected with the church attached thereto, was read a third time and passed. The Chloride, &c. Protection Bill was also read a third time and passed.

Sewage of London.

In the House of Commons on Friday, August 8th, in reply to Mr. Borlase, Sir C. Dilke gave explanations as to the amount and cost of the disinfectants employed in deodorising the sewage of London. About twenty tons of perchlorides of lime, and between three and four tons of permanganate of potash, are used for the purpose, the cost for the latter being about £130, and of the former £9 per ton.

The Army Medical Department.

On Tuesday, Mr. Ross asked the Secretary of State for War whether the prefix "Royal" was to be omitted from the Army Medical Department, notwithstanding the recommendation of Lord Morley's Committee that it should be constituted a Royal corps. The Marquis of Harrington said the recommendation of Lord Morley's Committee referred to in the question was not a very strong one, and might perhaps be regarded rather in the light of a suggestion. Looking at the position of other military departments which had not this distinction, he did not think it desirable to act upon the suggestion of the committee.

Obituary.

SIR ERASMUS WILSON, F.R.C.S.

THE death of Sir Erasmus Wilson, late President of the Royal College of Surgeons, occurred at Westgate-on-Sea on the 7th inst. On the 23rd ult. Sir Erasmus attended at the consecration of St. Saviour's Church, Westgate-on-Sea, of which he had laid the first stone eleven months previously, and three days later he was attacked by inflammation of the bowels which terminated fatally. During the last twelve months he had endured the affliction of almost total blindness.

The son of a naval surgeon, James Erasmus Wilson was born in 1809. He obtained his professional education in London and Aberdeen, and became a Member of the College of Surgeons in 1831. He was appointed Demonstrator of Anatomy at University College. On the retirement, however, from University College Hospital of Mr. Jones Quain, Mr. Wilson severed his connexion with the institution and established the Sydenham College School of Anatomy, an undertaking which did not prove successful. He then commenced practice in Charlotte-street, Bloomsbury square, and there by means of taking pupils, and [illegible] on for some years. His father, after serving [illegible] navy, engaged a large mansion at Dublin, [illegible]

Digitized by Google

purpose of carrying on a private lunatic asylum, and it was here that Mr. Wilson became acquainted with the late Mr. Wakley, Coroner for Middlesex. Some time afterwards he was appointed sub-editor of THE LANCET, a position he held for about three years; after relinquishing this post, he was for a considerable time upon the staff of writers. He was appointed consulting surgeon to the Marylebone Infirmary, an appointment which he held during a great part of the time that the late Dr. Boyd was resident surgeon; here he had extraordinary opportunities of witnessing every phase of hospital surgery.

Having chosen skin diseases as his specialty, Mr. Wilson visited the East to make himself acquainted with leprosy. He went for his holidays to Switzerland and the Valais to examine goitre, and roamed over Italy with an eye rather to ringworm and the many cutaneous disorders of an ill-fed peasantry than to the artistic beauties of the country. Among the best known of his works are "The Dissector's Manual," "The Anatomist's Vade Mecum," "The Student's Book of Diseases of the Skin," "A Healthy Skin—a popular treatise on its management," "Report on Leprosy," the article on "Skin" in Cooper's Surgical Dictionary, and some elaborate Anatomical Plates. He also wrote articles and reports for journals of medicine and science, and was for a time correspondent on Surgery to the Academies of Medicine of Paris and Leipsic. It is unquestionable that Mr. Wilson knew more about skin diseases than any man of his time. He cured where others had failed to cure; and his works on Dermatology, though they met with pretty searching criticism at the time of their appearance, have nearly all maintained their position as text-books. The horrible cases of scrofula, anæmia, and blood poisoning which he witnessed among the poor of London—they are happily rarer now than they were half a century ago—enlisted his warm sympathies. But he had to deal with rich patients as well as poor, and over these the masterful stamp of his mind enabled him to exercise despotism in matters of diet. Wilson was not only a consummate dietician, but he knew how to make his patients submit to have their bodies placed under martial law.

The greatest incident of his career, however, and that which brought him into notice with the general public was the inquest at Hounslow upon the body of a soldier who had died after the receipt of a regimental flogging. This inquest was held by the late Mr. Wakley, and engaged the attention of the public for many days. After ten adjournments a verdict was given, owing in a great measure to Mr. Wilson's evidence, to the effect that death was caused by the flogging. This occurrence proved the death-blow to flogging in the army, and the inquest was soon followed by a Parliamentary inquiry, which resulted in that punishment being erased from the regimental code.

Professional honours were lavished on Mr. Wilson abundantly in reward of his labours. He became Fellow of the College of Surgeons in 1843, member of the Council in 1870, and President in 1881. In 1869 he founded, at his own expense, the chair and museum of Dermatology in the College of Surgeons, and was elected the first professor. He also instituted the chair of Pathology in the University of Aberdeen. In our last issue we announced that at a meeting of the Council of the Royal College of Surgeons the honorary gold medal of the College was awarded to Sir Erasmus Wilson in recognition of his great liberality in his contributions to the museum, in the endowment of the pathological curatorship, and in the foundation of the professorship with which his name will always be associated. Since this medal was founded in 1800 it has only been six times presented.

Erasmus Wilson erected a chapel and a new wing to the Sea-bathing Infirmary at Margate; he built the master's house at the Epsom Medical College in 1872; and restored the Church of Swanscombe, Kent, in 1873. For these and other similar acts of bounty Her Majesty conferred the honour of knighthood on Mr. Wilson in 1881; but by that time he had earned national fame of a new sort by bringing the obelisk—generally but inaccurately named Cleopatra's Needle—to England. This obelisk was one of two which had long lain in the sands at Alexandria. The French have one which has stood in the Champs Elysée since 1835. That which now adorns the Thames Embankment was acquired for Great Britain by Sir Ralph Abercromby in 1801; but it was not removed. It was offered to the British Government by Mehemet Ali in 1840, and again by the Khedive in 1877; but still the British Government did not think it worth while to incur the expense of transport. Erasmus Wilson thought this derogatory to the national dignity, and undertook to have the obelisk brought over at his own cost. This amounted to upwards of £10,000; but eventually it was brought to London, and the obelisk was placed in its present site in September, 1878.

Respecting his wealth, it is well known to all his friends that Sir Erasmus did not amass this merely as the result of his professional practice; it was the fortunate investment of his "guineas," which multiplied in various metropolitan companies, amongst which "gas" may be cited as wonderfully lucrative, and it has been stated that he was one of the largest shareholders in metropolitan and suburban gas companies. Railways, also, he dealt largely in, and always to his great benefit.

Sir Erasmus Wilson leaves no issue. He was married in 1841 to Miss Doherty, daughter of Mr. James Doherty, who survives him. A brother, Dr. Morris Wilson, who assisted him in his early practice, also survives him. We regret to say that this gentleman has been for the last twelve years utterly prostrate, suffering from paralysis. In addition to this affliction, which he has borne with Christian patience, Dr. Marris Wilson also suffers from total blindness.

The funeral of Sir Erasmus Wilson took place on Wednesday, when his remains were interred in Swanscombe Churchyard.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen passed the Primary Examination for the Licence on August 7th:—

C. R. Adams, J. V. Albart, G. R. Anderson, J. R. Anderson, J. W. Applegate, E. A. Armstrong, G. C. B. Atkinson, J. C. Baines, G. T. C. Barber, A. M. Barford, W. J. T. Barker, W. B. Barnard, H. N. Baron, H. C. Barr, J. C. Barr, E. Barrett, S. E. Barrett, W. J. Bearblock, J. Beddow, J. H. Blakeney, W. Bowden, W. G. Bower, J. A. Bradbury, F. C. Brodie, H. Browne, R. H. J. Browne, A. J. Bulger, H. M. Burke, A. Carter, A. L. Castel, C. D. Christmas, F. W. Clark, W. B. Cockill, S. J. Cole, H. S. Collier, A. W. Cooke, T. S. Coombe, H. A. W. Coryn, J. J. Coulton, E. Creighton, E. W. Crossley, H. Dane, F. M. Davies, G. C. Davis, J. P. De Buriatte, A. J. De Butts, E. A. G. Downing, H. E. Drake-Brockman, C. H. Eccles, A. D. Edginton, G. A. Etsell, H. H. Ellis, W. N. Evans, F. W. Farr, W. Fisher, W. F. Fisher, J. R. Gallard, T. W. Gibbard, J. H. Gilbertson, J. C. Gilmour, J. Girling, J. Good, L. D. Gover, C. T. Griffiths, B. Hamilton, H. Hamilton, E. B. Harris, P. R. T. Harris, F. S. Hawkins, W. H. Athey, H. H. Heffernan, A. G. Hendley, R. G. Hicks, C. M. Hill, C. U. P. Hogarth, E. B. Holland, A. K. Holt, H. Holyoake, S. P. Hosegood, W. L. Hubbard, A. H. W. Hunt, W. R. Y. Ives, A. W. James, P. D. James, J. H. E. Jarvis, H. H. Joslen, L. E. Jowers, T. W. Kelly, G. D. Kerr, E. E. Kershaw, T. M. King, H. W. Knowles, E. L. Lancaster, W. H. Lane, C. B. T. Langton, E. T. Latham, H. Layne, B. A. Lewis, H. W. Lewis, H. Lloyd, A. Lucas, K. W. I. Mackenzie, H. H. B. Macleod, C. T. B. Maisey, R. E. Mann, H. R. Manser, H. B. Marriott, G. Michelmore, J. Moore, F. B. Morse, W. Mortimer, J. E. Moyes, W. G. Nash, F. Naumann, S. Nicklin, J. Nixon, J. Norton, F. Osborne, A. D. Owen, A. T. Ozzard, F. Pain, F. W. Parker, W. Parker, G. W. F. Paul, W. P. Peake, H. J. Pocock, J. E. L. Pollard, A. F. Poolman, T. M. Porter, E. E. Powell, W. Powell, P. Preebin, E. L. Puddicombe, S. W. Quartley, H. E. Rayner, B. Raines, G. W. Richards, A. Rigden, T. W. Robbins, C. D. H. Rogers, J. C. V. Sapp, W. J. Scott, H. B. Seddon, H. F. Semple, R. W. Senior, R. R. Siemen, F. J. P. Smith, H. Smith, E. A. Snape, H. Stelfox, P. W. Sweatfield, P. C. H. Strickland, W. C. Swayne, F. R. P. Taylor, J. Thomas, T. N. Thomas, W. Thompson, A. Turner, W. Venis, W. H. Vickery, C. S. Vines, C. H. Wade, R. F. Waites, C. H. Walsham, R. V. Walsh, A. H. Ward, W. Watkins, R. E. Wellington, H. F. Wiltchurch, E. R. White, J. H. White, G. R. Williams, J. F. Williams, A. Wilson, J. W. Winterbotham, F. D. Woodhouse, W. Woodward, W. L. Woolcombe, G. C. W. Wright.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 7th inst.:—

Dumbleton, Charles Eardley, L.S.A., Tasmania.
Godfrey, H. J. Clatterdon, L.R.C.P. Edin., Lee-park.
Hooge, William Theodore, Middleton.
Mathews, H. E. Hamerton, L.R.C.P. Edin., Longsight, Manchester.
Reily, Alexander Yates, L.S.A., South Norwood-hill.
Shepherd, Lionel John, L.R.C.P. Edin., Torquay.
Spong, Charles Stuart, L.S.A., Clapham.
Visger, Harman, L.S.A., Clevedon, Somerset.
Waite, Henry, L.R.C.P. Edin., Leeds.

Admitted Members of the College on the 8th inst.:—

Allen, Sydney Glean, L.R.C.P. Edin., Maida-vale.
Evans, Tegid Aneurin, L.R.C.P. Edin., Clapham.
Greenway, John Henry, L.S.A., Belvedere.
Hinds, Frank, L.S.A., Goudhurst, Kent.
Humphreys, Charles Evan, L.S.A., Llanfair, Welshpool.

Digitized by Google

Low, Charles William, L.R.C.P.Lond., Plumstead.
Milner, James, L.R.C.P.Edin., Barnsley, Yorks.
Robertson, James Sprent, L.S.A., West Kensington-park.
Tomalin, W. J. Clarkson, L.S.A., Northampton.

The Final Examination for the Membership of the College, which commenced on July 18th, was brought to a close on August 8th. Of the 365 candidates examined, 149 passed to the satisfaction of the Court of Examiners and obtained their diplomas; 75 passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members; the remaining 141 failed to reach the required standard, and were referred to their further professional studies. Forty-two candidates who had passed in Surgery at previous examinations, having subsequently obtained a Medical degree or licence recognised by the College, were also admitted Members. This is the last examination for the Membership of the College until October. The Museum and Library will be closed as usual during the month of September for the necessary repairs, painting, &c.

UNIVERSITY OF LONDON. — The following candidates have passed the recent Intermediate Examination in Medicine:—

ENTIRE EXAMINATION.

FIRST DIVISION.

Alexander, Sidney Robert, Guy's Hospital.
Bahadurji, Kaikhosro Nasarvanji, University College.
Balgarnie, Wilfred, St. Bartholomew's Hospital.
Biddlecombe, Edward Henry, St. Bartholomew's Hospital.
Bradford, John Rose, B.Sc., University College.
Brook, William Henry Breffit, St. Bartholomew's Hospital.
Brown, Frederick Nathaniel, St. Bartholomew's Hospital.
Burghard, Frédérick François, Guy's Hospital.
Chitty, John Shaw Willes, Charing-cross Hospital.
Clarke, James Jackson, St. Mary's Hospital.
Clarke, William Frederick, Guy's Hospital.
Featherstone, William Barltrop, Queen's and Mason Colleges, Birmingham.
Helme, Thomas Arthur, University of Edinburgh and University College.
Lawrence, Thomas William Pelham, University College.
Lyndon, Arnold, St. Bartholomew's Hospital.
Macevoy, Henry John, B.Sc., St. Thomas's Hospital.
Mariette, Ernest Paul Alphonse, King's College.
Rowell, George, Guy's Hospital.
Smith, John Anderson, St. Bartholomew's Hospital.
Thompson, James Edwin, Owens College.
Tomlinson, William Henry, Owens College.
Tonking, John Herbert, St. Thomas's Hospital.
Toogood, Frederick Sherman, University College.
Trevelyan, Edmond Fauriel, St. Bartholomew's Hospital.
Wheatley, James, King's College.

SECOND DIVISION.

Ashworth, John Wallwork, Owens College.
Barclay, Wilfred Martin, Bristol Medical School.
Bindley, Robert Alfred, Guy's Hospital.
Blackler, Henry John, Guy's Hospital.
Bowman, Henry Claxton, Owens College.
Brazil, Walter Henry, Owens College.
Brown, Herbert Henry, University College.
Burrell, Arthur William, London Hospital.
Castle, Bernard, St. Bartholomew's Hospital.
Davis, Arthur Holdsworth, St. Bartholomew's Hospital.
Dobson, Leonard Charles Talbot, St. Bartholomew's Hospital.
Elliott, William Henry Wilson, Guy's Hospital.
Furnivall, Bryan, St. Bartholomew's Hospital.
Gardner, William Thomas, St. Bartholomew's Hospital.
Gault, Arthur Henry, Owens College.
Gee, Frederick William, University College.
Godfrey, Albert Edward, St. Thomas's Hospital.
Greig, Duncan McBean, University College.
Hamel, Julius, University College.
Hensley, Philip Henry, King's College.
Holder, Sydney Ernest, University College.
Jordan, Walter Ross, Queen's and Mason Colleges, Birmingham.
Kauffmann, Otto Jackson, Owens College.
Lindow, Albert, King's College.
Luff, Arthur Pearson, B.Sc., St. Mary's Hospital.
Lys, Henry Grabham, London Hospital.
Moore, Robert Lee, Queen's College, Belfast.
Nevins, John Ernest, Guy's Hospital and Liverpool School of Medicine.
Pagden, Trayton Charles, St. Bartholomew's Hospital.
Permewan, William, University College.
Pugh, John Williamson, London Hospital.
Rivers, William Halse Rivers, St. Bartholomew's Hospital.
Seville, Charles Frederick, Owens College.
Smith, Hugh, Guy's and London Hospitals.
Solly, Ernest, St. Thomas's Hospital.
Spencer, Walter George, St. Bartholomew's Hospital.
Sunder, Charles Edward, University College.
Swayne, Walter Careless, Bristol Medical School.
Wheaton Samuel Walton, St. Thomas's Hospital.
Wheeler, James Atkin, Guy's Hospital.
Young, Charles Wheeler Forest, St. Bartholomew's Hospital.

EXCLUDING PHYSIOLOGY.

FIRST DIVISION.

Smith, Henry Ernest Hill, King's College.

SECOND DIVISION.

Green, Albert, Guy's Hospital.
Kelson, William Harry, London Hospital.
Oliver, Charles Pye, Charing-cross Hospital.
Risdon, William Newt, Guy's Hospital.
Stewart, Arthur Hastings Lanfear, St. Mary's Hospital.

PHYSIOLOGY ONLY.

FIRST DIVISION.

Eady, George John, King's College.
Taylor, Charles Henry, King's College.
Wynter, Walter Essex, Middlesex Hospital.

SECOND DIVISION.

Ackland, Charles Kingsley, King's College.
Williams, Reginald Munro, St. Thomas's Hospital.

The name Nicholas Charles Ridley (St. Mary's Hospital) was inadvertently omitted from the list published last week of gentlemen who passed the Preliminary Scientific Examination of the University.

UNIVERSITY OF ABERDEEN.—During the past year the following candidates received the degree of M.D.:—

Brand, Alexander Theodore, M.B., C.M., Driffield, Yorkshire.
Brown, William Carnegie, M.B., C.M., Penang.
Davies, Morgan, M.B., C.M., Llangwyryfon, Cardiganshire.
Fehrsen, Frederick John, M.B., C.M., Kingston, Jamaica.
Findlater, Sylvester Williamson, M.B., C.M., Dufftown.
Footner, Edward, M.B., C.M., Brigade Surgeon.
Hodgson, Joseph Willoughby, M.B., C.M., Exmouth, Devon.
Jones, Timothy Siddall, M.B., C.M., Swansea.
Knowles, Edward, M.B., C.M., Birkenhead.
Le Mottée, G. H., M.B., C.M., Army Med. Depart., Chatham.
Low, Charles, M.B., C.M., Arbroath.
Millar, James, M.B., C.M., Arbroath.
Moir, John Hay, M.B., C.M., Burton-on-Trent.
Murray, John, M.B., C.M., Surgeon-Major, Ipswich.
Nicol, Alexander, M.B., C.M., Inverurie.
Phillips, Henry Astley, M.B., C.M., Waterbeach.
Robb, J. Bernhardt Klingner, M.A., M.B., C.M., Montrose.
Tuckey, Charles Lloyd, M.B., C.M., London.
Walker, James Hutchison, M.A., M.B., C.M., North Borneo.
Wilde, Percy Roberts, M.B., C.M., Bath.

The following received the degrees of M.B. and C.M.:—

Adamson, Henry M'Kenzie, Morphie, Montrose.
*Allden, George Henry, Southampton.
Anderson, John Hector, Aberdeen.
Anderson, Joseph, Preston.
Barrett, Albert Henry, Wallingford, Berkshire.
Battiscombe, Christopher George, Blackheath.
Bennet, Francis Alexander, M.A., Cullen.
Bett, James Wilson, Dundee.
*Clark, William Ronaldson, M.A., Edinburgh.
Cook, James Will, Alness.
Cowie, Alexander Mitchell, Mortlach.
Craig, James Forsyth, M.A., Leslie, Insch.
Currie, George Burnett, M.A., Aberdeen.
Dalton, Henry Moger Cyril, Newcastle, New South Wales.
Davidson, Alexander Gordon, M.A., Wartle, Aberdeenshire.
Duffus, George, Cullen.
Duguid, Alexander Gray, Longside, Aberdeenshire.
Elmslie, Walter Angus, Resthawet, Chapel of Garioch.
Faulkner, Charles Albert, Rajahmundry.
Fehrsen, John Andrew, Graaf Reinet, South Africa.
Forster, William Revely, Blyth, Northumberland.
*Gibson, Thomas Best, M.A., Aberdeen.
*Gordon, John, Keith.
Graham, Thomas Bell, Ecclefechan.
Grant, Andrew, Balmoral.
Harrisson, John William, Sandwich, Kent.
Lyall, Charles Robert, Aberdeen.
Macdonald, Stuart, Elgin.
Mackintosh, Frank James, M.A., Deskford, Cullen.
Maclean, Alexander, F.R.C.S. Ed., Thurso, Caithness.
Maclennan, Andrew Anderson, Nairn.
Milne, George, Methlic.
Mitchell, James, Aberdeen.
Munro, James Mitchell, Inverurie.
Murchison, Alexander, Lochearron.
Poonen, Eapen, B.A., India.
Pressile, Robert Dowell, Aberdeen.
Reid, Alexander, Auchindoir.
Reid, Irvine Kempt, Aberdeen.
*Roberts, Alfred Ernest, London.
Robertson, William, M.A., Rathen.
Russell, John, Longhope, Orkney.
Ruxton, William Ledingham, West Riding Asylum, Wakefield.
Savege, James, Montrose.
Simpson, Patrick George, Aberdeen.
Sutherland, William Leith Ireland, Aberdeen.
Thiele, Herman, Bermuda.
Walker, Leslie Fyfe, Aberdeen.
Webb, John Eustace, Windsor.
*Will, James, Ellon.
Windle, John Thomas, Burnley.
Young, James Martin, Boyndlie, Fraserburgh.

* Received their Degrees with Honourable Distinction.

The John Murray Medal and Scholarship were awarded to Arthur Greatorex Smith, and will be presented to him along with his diplomas on his attaining the necessary age.

ROYAL COLLEGE OF SURGEONS IN IRELAND. — The undermentioned gentlemen were admitted Fellows of the College at recent examinations:—

Boyd, H. W. B. A.M.D.
McCarthy, Charles William.

Digitized by Google

APOTHECARIES' HALL. — The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 7th:—

Bass, Howarth Dentman, Smith-hill Bank, Hampstead.
Carr, John Walter, Bloomsbury-square.
Joberns, William, Aldridge, Walsall.
Waddington, William Tasbman, Kingsford-road.
Spong, Charles Stuart, Clapham.
Viger, Harman, Brompton-road.

The following gentleman also on the same day passed the Primary Professional Examination:—

Pemberton, John Oliver, London Hospital.

ELECTION OF EXAMINERS. — The following gentlemen have been elected Examiners by the Society of Apothecaries for the ensuing year:—Henry Balleek, F.R.C.S. Esq., Drs. Alfred Carpenter, Henry R. Crocker, Robert Fowles, F. de Havilland Hall, Frederick J. Hensley, Robert J. Lee, W. Withers Moore, George H. Savage, John S. Stocker, John C. Thorowgood, and Francis Warner.

BY a majority of twelve to seven the Banbury Board of Guardians have decided not to enforce the Vaccination Act in the town and district.

AT Wetherby Petty Sessions, on the 7th inst., a lodging-house keeper was fined £1 and costs for having wilfully exposed a domestic servant, whilst suffering from an infectious disease—scarlet fever.

SEVERAL cases of death from lightning-stroke have been reported this week. Lamentable occurrences of this kind are often the result of thoughtless disregard of precautions which have been repeatedly indicated

WORKING LADS' INSTITUTE. — Her Majesty the Queen has, through Sir Henry Ponsonby, given her patronage and a contribution of £50 towards the building fund of the Working Lads' Institute, The Mount, Whitechapel, London, E.

AT the Stratford Petty Sessions, on Wednesday, a costermonger was fined 10s. and costs for throwing offal on the public highway. The defendant pleaded that he was unaware that he was breaking the law in thus disposing of his refuse.

A SUBSCRIPTION has been opened at St. Petersburg in order to raise the money for instituting at the University five bursaries in the name of Charles Darwin, to be employed for the maintenance of five students in the five chief branches of Natural Science.

SUICIDE OF A SURGEON.—At an inquest held at Aylesbury, on the 6th inst., on the body of George David Widdas, M.R.C.S., the jury returned a verdict that deceased destroyed himself by taking chloral hydrate, but that there was not sufficient evidence to show the state of deceased's mind at the time.

BEQUESTS.—The late Mr. W. J. Patterson has bequeathed £1000 to the Royal South Hants Infirmary, £500 to the Southampton Dispensary and Humane Institution, and £150 to the St. Mary's Cottage Hospital. The late Mr. Francis Parnell has left £105 to the Manchester Royal Infirmary.

HERTFORD CORPORATION TOWN WATERWORKS.—The Abyssinian tube-well, for the entire supply of the town of Hertford, has been recently completed, with satisfactory results. The size of the tube-well is seven inches and a quarter, and at the depth of eighty-one feet the chalk springs are so abundant that the yield is over 100 gallons per minute. The motor power for pumping is obtained from a water-wheel worked by the river Lea.

THE JOHN REID PRIZE.—The prize founded by the sister of the late John Reid, surgeon, Glasgow, in memory of her brother, is awarded for the best original research bearing on any of the departments of medical science conducted in one of the hospitals or laboratories of Glasgow. The prize, which is of the annual value of £25, was, at a meeting of the trustees held yesterday, awarded for two years to Mr. H. Lyon Smith, who conducted in the Pathological Laboratory of the Royal Infirmary an investigation into the Changes found in the Circulation through the Kidney in certain Pathological Conditions. As a recognition of the high standing of a paper on the Bacillus of Tubercle, sent in by Mr. Leonard Williams, the trustees awarded him £10. This investigation was conducted in the Western Infirmary.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

CLAREMONT, LOUIS BENNETT, M.R.C.S., has been appointed Medical Officer to the No. 2 District of St. Pancras Union, vice Hall, deceased.

CUPP, ROBERT, M.B.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Rural District of the Scarborough Union.

HAINES, ALFRED HENRY, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Tydd District of the Holbeach Union, vice O'Meara.

HICKS, CHARLES CYRIL, M.D. St. And., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Wokingham District of the Wokingham Union, vice Cresswell.

JACK, CHARLES, M.D., C.M.Glasg., has been appointed Medical Officer of Health to the Horsforth Urban Sanitary District, vice Libbey.

JONES, T. W. CARMALT, M.A.Camb., F.R.C.S.Ed., has been appointed Assistant-Surgeon to the Western Ophthalmic Hospital.

KEYWORTH, JOHN WHITE, M.D.Lond., M.R.C.S., has been appointed Resident Medical Officer to the Wellington Hospital, New Zealand.

KING, ERNEST EDWARD, M.R.C.S., L.S.A.Lond., has been appointed Resident Obstetric Physician to the Middlesex Hospital.

KITCHEN, CHAS. F. HEWICK, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to the Cheetham District of the Prestwich Union, vice Crean.

KNOX, Dr. D. N., has been appointed Surgeon to the Royal Infirmary, Glasgow, vice Morton, whose term of office expires on Nov. 1st.

NEWMAN, ARTHUR JOSHUA, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Farncombe District of the Guildford Union, vice La Fargue.

POPPLEWELL, THOS. WM., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Blisworth District of the Towcester Union, vice Cresswell.

PRINGLE, J. J., M.R.C.P. (of Bruton-street), has been elected an Assistant-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Dr. Coxwell, resigned, on going abroad.

RAY, HENRY, M.B., Ch.M.Glasg., L.R.C.P., L.R.C.S.Ed., has been appointed Honorary Medical Officer to the Goulbourn Hospital, New South Wales.

ROBERTSON, ALEXANDER, M.D.Glasg., F.F.P.S.Glasg., has been appointed Physician to the Royal Infirmary, Glasgow, vice Dr. James Maclaren, resigned.

SMART, DAVID, L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse in the Tenteth Park Township.

TRAVIS, W. OWEN, M.S., M.B.Durh., M.R.C.S., has been appointed Demonstrator of Anatomy in the Yorkshire College, Leeds.

WHITSON, Dr., has been appointed Assistant-Surgeon to the Royal Infirmary, Glasgow, vice Dr. Lothian, promoted.

WOOD, WILLIAM, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Cranswick District of the Driffield Union, vice R. Wood, resigned.

Births, Marriages, and Deaths.

BIRTHS.

CLAY.—On the 8th inst., at Windsor-villas, Plymouth, the wife of R. Hogarth Clay, M.D., of a daughter.

COLGATE.—On the 5th inst., at Burlington-place, Eastbourne, the wife of Henry Colgate, M.D., F.R.C.S., of a daughter.

CONNOLLY.—On the 7th inst., at Wickham-road, Brockley, Kent, the wife of Surgeon-Major B. B. Connolly, Army Medical Department, of a son.

GRANGE.—On the 6th inst., at Moffat, N.B., the wife of William D'Oyly Grange, M.D., of a son.

HEYGATE.—On the 4th inst., at Wellingborough, the wife of F. N. Heygate, M.R.C.S. &c., of a son.

VLIELAND.—On the 5th inst., at Sydney Lodge, St. Thomas, Devon, the wife of C. J. Vlieland, M.R.C.S., of a daughter.

YOUNG.—On the 17th ult., at Beqeia, St. Vincent, West Indies, the wife of James Vance Young, M.D., of a son.

MARRIAGES.

JEWEL—TUCKER.—On the 5th inst., at St. Peter's Church, St. Pancras, Henry Jewel, M.D., to Kate, second daughter of Mr. C. Tucker.

PARKER—BICKERTON.—On the 7th inst., at St. Bride's, Liverpool, Rushton Parker, B.S., F.R.C.S., of Rodney-street, Liverpool, to Catherine Elizabeth, daughter of the late Thomas Bickerton, Surgeon, of Liverpool.

DEATHS.

BARRAUT.—On the 17th ult., at St. George's-street, Port Louis, Mauritius, Adolphe Rodrigues Barraut, M.D., aged 49.

CAMPBELL.—On the 8th inst., at Warley, Brentwood, Essex, D. Cochrane Campbell, M.D., M.R.C.P., second son of the late Rear-Admiral Campbell, of Barbreck, Argyleshire.

HARRIS.—On the 7th inst., at Buckingham Lodge, Vansittart-road, Torquay, Surgeon-Major F. W. Harris, late Bombay Army, aged 62.

REID.—On the 13th inst., at Madeira-road, Streatham, Alexander William Watson Reid, Surgeon, Royal Navy.

WATSON.—On the 7th inst., Henry Watson, Surgeon, late of Plumstead, aged 84.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

BOGUS AMERICAN DEGREES.

THE following extract from *The Times*, a telegram from one of its correspondents, should be pondered by all who are concerned in either the purchase or the sale of bogus degrees:—"The defunct Medical University of Philadelphia, re-baptised Hospital College, Cambridge and trouble by selling bogus diplomas, has reappeared. The English Consul at Philadelphia, Mr. Clipperton, states that he is in receipt of letters from various parts of Great Britain asking for information about the standing of the College, and to what extent its diplomas are accepted. The Government has thus done all in its power to kill the illegal traffic in diplomas, by cancelling the charter of the College and closing it. If impostors are still committing fraud upon the public through agencies in England, they should be prosecuted by the British authorities."

THE letter of Dr. Cullingworth arrived too late for insertion in our previous issue.

Dr. Stoker (Northampton).—Yes.

ARREST OF DEVELOPMENT OF THIRD RIB IN A FŒTUS.

To the Editor of THE LANCET.

SIR,—The following case, being one of rather uncommon occurrence, may be of interest to some of your readers.

On August 2nd I attended J. H., aged thirty-four years, in her first confinement. Labour commenced on Aug. 1st, at 9 P.M., and delivery took place at 4 A.M. next day. On the right of the infant I noticed a depression in the left mammary region, which, on careful examination, I found to be caused by the arrest of development of the third left rib three-quarters of an inch from the sternum, the free end of the rib being smooth and rounded off, and drawn in at each inspiration. There is a small nodule on the sternum, in the position of the third costal cartilage. The child, a female, weighs seven pounds, measures nineteen inches and a half, weighs six pounds, and is in all other respects well developed and healthy.—I am, Sir, yours faithfully,

Shipley, Yorks, Aug. 9th, 1884. PARRY CARTER, M.R.C.S.

Mr. B. F. Solymos, C.E.—Undoubtedly, one of the principal aims at in wearing flannel or merino next the skin is obtained when the undervest is lined with linen or cotton.

Mr. D. Wilson (Glasgow).—We know nothing of the nostrum.

OPIUM CULTIVATION IN RAJPUTANA.

In consequence of the extension of irrigated works in the province of Rajputana, in India, and the opening of the Rajputana-Malwa Railway, affording the produce easy access to Bombay, poppy cultivation has been considerably on the increase within the last two or three years.

Mr. Rea Edwards.—The paper is received for insertion, and after use the block will be at the disposal of the author.

PREVENTION OF "HARVEST BUGS."

To the Editor of THE LANCET.

SIR,—Hygienic treatment, as a matter of course, is an important factor in preventing attacks of "harvest bugs"—e.g., the clothes of such children should be destroyed, or be exposed to a temperature of at least 150° F., by steaming them, ironing them over with a sufficiently hot iron, or boiling them.

For external application: Calvert's or Macdougal's carbolic acid soap or ointment, or, as a lotion in the following proportions, will be found beneficial: Crystallised carbolic acid, two drachms; spirits of rosemary, an ounce; rectified spirit, half an ounce; distilled water to make up a lotion of six ounces, with which the parts are to be sponged night and morning. Sulphur may be used in the form of vapour baths or fumigations, or the simple or compound ointment of sulphur of the Pharmacopœia with some lavender water. Mercury may also be employed as simple mercurial ointment, or by fumigations with cinnabar, or in solution of the bichloride, in the proportion of ten or twelve grains to an ounce of water, to which some alcohol has been added. The application of sulphurous acid as recommended by Mr. Starkin, seems beneficial: "A warming-pan containing live coals sprinkled with sulphur should be put between the clothes till the sulphur is consumed. A damp napkin held before the mouth will prevent the fumes from entering the lungs." It seems better, however, to submit the bedding (in which cannot be boiled for some hours) to a temperature between 150° and 200°, in a disinfecting chamber or oven. The quickest way of curing and destroying the parasite is to immerse the patient, leaving the head free, in a gaseous bath of sulphurous acid, made by burning twelve ounces of sulphur to a suitable disgrace. While in the bath the patient should be baked, so that in boiling hot water he is saved from irksome pains, and is made free from risk of reinfection.

Internally, the administration of iodide of potassium in small doses, according to age, &c., seems to render the system unsuitable for any further development of the acarus in animals.

I am, Sir, yours obediently,

Osborn place, W.C., Aug. 9th, 1884. C. S. TAYLOR, M.D.Brux.

To the Editor of THE LANCET.

SIR,—I think if Dr. Fox will use a few quassia chips in the morning bath, and sponge the exposed parts of the person with a weak infusion of the quassia once or twice daily, he will find there is complete protection from almost all the annoying insects found in our fields. Even mosquitos fight shy of a person so protected.

I am, Sir, yours faithfully,

St. Leonard's-on-Sea, Aug. 12th, 1884. JOHN T. FINNEY.

METHOD OF TREATING SPRAINS.

To the Editor of THE LANCET.

SIR,—Allow me to remark that in the new method of treating sprains by Mr. Thos. J. Shearer, as published in your last issue, the efficacy lies probably solely in the compression applied through the day, by the knitted joint, by the rubber roller bandage, and not in any to a peculiar discipient property of the clay itself, which could be omitted without the least inconvenience. Thus modified, the method has been contrived and applied, I think for the first time, by M. Marc Sée, who has described it as a kind of compound treatment, combining rest with rubbing or massage, in the *Revue de Chirurgie* of Jan. 10th, 1884. If Mr. Shearer will try the rubber roller bandage alone, without adjunction of clay, he will have undoubtedly the same good results.

I am, Sir, yours truly,

Rue Marignan, Paris, Aug. 9th, 1884. DAVID DININ.

M. C. de Courcy Morris.—The case is one in which the fee should be divided equally.

Mr. Rankin's letter arrived too late for notice this week.

VACCINATION AND SMALL-POX.

To the Editor of THE LANCET.

SIR,—The following case corroborates the article in your issue of the 2nd inst., headed "Vaccination v. Small-pox." Some years ago, during an epidemic of small-pox in Liverpool, I vaccinated an infant [illegible] old. The vaccination was successful, but when the child was [illegible] weeks old the mother took small-pox, and although she continued to suckle the child, it did not take the disease. I remember that during the same epidemic I vaccinated [illegible] on two occasions, but without success, [illegible] on being in the neighbourhood. The vaccination was successful in both cases.

I am, Sir, yours truly,

Liverpool, Aug. 9th, 1884. JOHN SINCLAIR, M.R.C.S.

Mr. Vincent Pleasant (Liverpool).—This investigation [illegible] January.

Digitized by Google

Mr. W. F. Macdonogh.—The works needed for examinations for the posts of inspector of nuisances, surveyor, and medical officer of health necessarily differ materially in some respects. There are, however, certain points which they have in common, and these will be found in (1) Dr. Wilson's Handbook of Hygiene, (2) either Mr. Bailey Denton's or Mr. Baldwin Latham's Sanitary Engineering, and (3) the Annotated Model Bye-laws issued by Messrs. Knight and Co., official publishers to the Local Government Board. The official orders relating to the duties of inspector of nuisances and medical officer of health should also be carefully studied.

Messrs. Burroughs and Wellcome.—Application might be made to the Director-General of the Army Medical Department.

"PRICKLY HEAT."

To the Editor of THE LANCET.

SIR,—In a communication on this subject which appeared in your issue of Aug. 2nd the writer relates a case which occurred in his practice in this country, and suggests a remedy. Thinking that perhaps others may have met with similar cases, and, having seen and treated a large number of cases on board ship in India and other parts of the East, I beg to offer the result of my experience. I have never seen a well-defined case in England; and when it does occur it would be most likely to do so in those who have resided in tropical countries, and have been victims to this disease during their sojourn there. There is no doubt that one attack predisposes to another. The disease is ushered in by a feeling of heat or glow over the body, but principally in the skin of the back, and in a few hours numerous little raised spots appear, which tingle and prick (one cannot call it itching) in a most unendurable manner. No one who has not seen a bad case, or had the sensation to a certain extent in his own person, would believe what torment it gives rise to. I have seen on board ship an Englishman, half maddened with this torture, fall on his knees in his cabin, and in all seriousness pray that he might die. It is almost always worse on the back than anywhere else, and does not often affect the extremities. It attacks elsewhere have been yeast in their strength quite as much as those who have just gone out for the first time, but I have never met with a case in a native. Now, as regards the remedy. The treatment is always more or less unsatisfactory, and everything that can be thought of has been tried in various cases. Clothing has, of course, much to do with it. In England, where the temperature is so various and uncertain, perhaps a very thick woollen jersey may be a good thing; but in India, where one can tell one day almost to a degree what the temperature will be the next, and where rainy and dry seasons alternate with such regularity, I used to find that woollen or flannel next the skin almost invariably aggravated the irritation. I always advised the wearing of an ordinary white calico shirt next the skin, and patients almost always found this more comfortable than anything else. The two remedial measures which I found more efficacious than any others were a bath twice a day in fresh water with ordinary washing soda dissolved in it, in the proportion of about a pound to four gallons; and the same bath without the soda, but with the addition of carbolic soap, with which the body should be thoroughly well washed. Various measures are recommended, and I have tried many of them; but I found these mentioned the best. I generally met with more cases of it in the wet season than in the dry, and more in Calcutta and the Eastern side of India than in Bombay. It is particularly prevalent in the months of September and October, when the hot sun is pouring its rays down upon ground saturated with recent and long-continued rain.

I am, Sir, yours truly,

[redacted] R. K. CRAIGIE, M.R.C.S., L.R.C.P. Lond.

[redacted] Aug. 7th, 1884. Late Surgeon P. & O. S. N. Co.

[redacted] POWER OF ELECTRICITY

To the Editor of THE LANCET.

SIR,—The following instance of the power of electricity to excite muscular action may be worthy of notice.

Two months ago I was in attendance upon a woman in confinement. At the termination of the labour the child was born apparently lifeless, and for fifty-five minutes failed to make a single inspiration, although artificial respiration and other means were used to restore animation. In the meantime I sent to my house for my electric battery, and immediately on applying the induced current to the chest and back I had the satisfaction of seeing muscular contraction take place in the muscles of the back and neck, and very shortly circulation was re-established and breathing became regular. The child lived for two days, and died after a convulsive fit. Under the stimulation of animation [illegible] from asphyxia of the heart's muscle, and that the blood was still possessed of vitality, I hoped that by starting the heart into action and driving onward the blood I might bring back the child to animation. The [illegible] to assume a muscular irritability in the [illegible] to allow of the efficient use of electricity. This case seems to show [illegible] the use of [illegible] never have breathed again had not the battery been used.

I am, Sir, yours truly,

C. H. HUNTABLE, M.D., M.Ch.

[redacted], June 4th, 1884.

"LUNACY NOT INCREASING."

AT length the facts are forcing themselves on the intelligent consciences of the official mind, and even being made apparent to the public. The *Daily News* of Aug. 13th says:—"The Commissioners in Lunacy observe in their recent report that the large annual addition to the number of insane persons under care has produced an impression that insanity itself is much on the increase. An examination of the figures which the report presents, however, shows that the apparent increase is almost entirely due to accumulation of chronic cases of the pauper class; so that, as the Commissioners observe, the community at large does not appear, from the official statistics, to be any more liable than formerly to be attacked by this terrible malady." *Magna est veritas et prævalebit.*

F.R.C.S. and other correspondents.—The circular enclosed would seem to be of the ordinary trading character, and appears offensive on account simply of its being sent by an undertaker.

TREATMENT OF VARICOSE VEINS.

To the Editor of THE LANCET.

SIR,—In a leading article of THE LANCET of May 3rd, 1884, it is stated that the only radical cure for varicose veins known is excision of a portion or the whole of the vein. I have waited to see if anybody at home would correct this statement. There being no such correction in your journal up to May 17th, the last number received here, I feel it incumbent on me to draw your attention to an article in THE LANCET of June 6th, 1874, p. 791, where it is stated that M. Simon of Verviers has used the perchloride of iron with great success. I can confirm this statement; for, ever since, now ten years, I have employed this same with unfailing success in varicose veins of the legs. The solution recommended by M. Simon is nearly the same as the liq. ferri perchlor. B.P. (the milder solution), which I use. The only modification I substitute is absorbent lint for flannel, as used by M. Simon, for compress; nor do I wring the pledgets dry, as recommended by him, but leave them moist; it seems to me to act more readily. I have just succeeded in curing an old gentleman aged seventy years, who has been suffering from varicose veins of the right leg for forty years. For the last few months the pain has been excruciating, the patient getting little or no sleep, and being totally incapacitated for business. He had a large ulcer extending from the external malleolus along the outer edge of the tibia half round the back of the leg, considerably larger than the palm of the hand. I drew pieces of strapping across the ulcer in the ordinary way, then applied pieces of absorbent lymph two or three inches long, slightly rolled, soaked in the solution of perchloride of iron, and applied them as compresses lengthwise on the veins. They were supported *in situ* by a bandage of thin flannel, called "domet," or "dumet," instead of the ordinary flannel, as it adapts itself better to the limb. This is reapplied every day for a week; then every other day. In a fortnight the varices had all disappeared, and the veins could be felt as hard wires under the skin. In six weeks the ulcer was healed, and the patient is now able to take long walks and attend to his business as accountant. I think the same may be applied to varicocele, though strapping would probably be required to retain the compresses *in situ*.

I am, Sir, yours truly,

J. E. H. LEWELLIN, M.R.C.S.

Prahran, Victoria, Australia, June 30th, 1884.

IS DEAFNESS A BARRIER TO PRACTICE?

To the Editor of THE LANCET.

SIR,—I cherish the hope that the kind sympathy of those interested like myself will prompt them to reply to this letter. My case is as follows. I possess a very important high-class practice, am devoted to my profession, and have a young family dependent upon me for their education and start in the world. I have just attained my fiftieth year, but am becoming very deaf, and have now some difficulty in hearing anyone unless the voice is raised. The [illegible] suffering from chronic aural catarrh, which is a progressive disease, and my experience of the last few months has unmistakably revealed its progressive nature. Now, it would be a satisfaction for me to know if, in the experience of any of your readers, deafness, even so bad as to necessitate the use of a trumpet, would entirely debar one from practice. When a man is thoroughly established, and has the confidence and friendship of his patients, would deafness such as I refer to lead to make them lose faith in him, and so gradually forsake him? Of course, I take for granted that a competent assistant would be required in all cases requiring auscultation. Now, Mr. Editor, or any of your readers, could tell me of a case where a man with very considerable deafness has yet continued to hold the confidence of his patients, it would be a comfort to me and an encouragement to hold on and persevere. If, on the other hand, there is to be my retirement, much desirable as I am to my calling, and [illegible] to launch out into another business or profession. I must look the evil in the face, and, for the sake of my children, commence the task as it [illegible]

I am, Sir, yours truly,

July 12th, 1884. CONSTANT SUFFERER.

ERRATUM.—The reference to a book in Mr. Charles Hawkins's letter in our last number should have been "at page 113," and not 193.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

"Bradshawe" Lecture

ON THE

PATHOLOGICAL RELATIONS OF THE ABSORBENT SYSTEM.

Delivered before the Royal College of Physicians of London, August 18th, 1884,

BY G. HARE PHILIPSON, M.A., M.D., D.C.L.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, PROFESSOR OF MEDICINE IN THE UNIVERSITY OF DURHAM, SENIOR PHYSICIAN TO THE NEWCASTLE-UPON-TYNE INFIRMARY, ETC.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—The occasion of the present assembly of this College is for the delivery of the fourth Bradshawe Lecture. By the munificence of the widow of William Wood Bradshawe, of Andover and Reading, a Member of this College, a Master of Arts and a Doctor of Civil Law of the University of Oxford, a sum of money was bequeathed whereby a lecture might be delivered at this College annually, with the object of perpetuating the memory of her husband, it being stipulated that the subject of the lecture should have a bearing upon some question of medicine, and that the lecture should be delivered upon the 18th day of August, the anniversary of his death. The munificence of the benefactress and generous founder is well deserving of an expression of respectful and appreciative commendation, in that, while endeavouring to preserve the name of a loving husband, she was actuated with the laudatory idea of associating such with a formal discourse for the advancement of the profession to which he was devoted and which he adorned. This home-loving, studious, and scholarly man, who diligently cultivated his mind in literature and science, may therefore be fittingly extolled as an example for others to follow. His name will be justly venerated and transmitted in good repute, as well as that of his generous and devoted widow.

In undertaking the important duty that has been entrusted to me, I feel the honour and estimate the responsibility of the position. It shall be my earnest endeavour to justify the choice of our revered President, to whom I beg to offer my grateful acknowledgments for this distinctive mark of his favour.

I have selected the Pathological Relations of the Absorbent System as the title of the lecture. The absorbent system occupies a prominent place in relation to several important pathological processes and conditions, and is at the present time receiving considerable attention from histologists and pathologists. As illustrations of these relationships, it may be mentioned that this system is undoubtedly concerned in many septic conditions, and the late Messenger Bradley classified glanders, malignant pustule, snake-bite, dissection wounds, and erysipelas as forms of septic lymphangitis. Moreover, it is supposed to play an important part in relation to various zymotic diseases, such as plague, typhus and typhoid fevers, and diphtheria. The serous cavities are also now regarded as parts of the lymphatic system, and some cases of inflammation of serous membranes, for instance, of puerperal peritonitis are considered as being due to lymphangitis. Again, the absorbents are concerned in conveying to various parts of the body morbid products, such as those of cancer, syphilis, and tubercle, and thus of disseminating these diseases through the system. Again, they are often involved in connexion with diseases of internal organs. Some structures consist mainly of lymph-follicles and their chief diseases are associated with these follicles. Certain skin diseases, such as erythema, have been attributed to inflammation of lymph rootlets, and changes in the lymphatics seem to constitute an important element in the morbid anatomy of elephantiasis and several other affections. These illustrations will suffice to show the importance of the pathological relations of the absorbent system, and justify the selection of this subject for this commemorative lecture.

As an introduction to the consideration, it will be fitting that a short reference should be made to the anatomy and physiology of the absorbent system; for, without such a statement the pathological changes or the departures from the healthy state to those of disease could not be indicated with the same precision and comparative exactitude as this method will ensure. Having in regard, also, that physiology in its true acceptation is the science which treats of the conditions, phenomena, and laws of the life of the human body in the state of health, while pathology comprises the departures from such, manifested to the observer in disease, this process commends itself as the right and true way for this dissertation to be conducted.

The lymphatic and the lacteal systems together constitute the absorbent system. There is no essential difference between the two systems. The process of absorption has for one of its objects the introduction into the blood of fresh materials from the food and air, and of whatever comes into contact with the external or internal surfaces of the body; and, for another, the gradual taking away of parts of the body itself, when they need to be renewed. In both these offices, absorption from without and absorption from within, the process manifests some variety and a very wide range of action, and in both two sets of vessels are, or may be, concerned—namely, the bloodvessels and the absorbents. The lymphatic system may, therefore, be considered as an appendage of or supplementary to the blood-vascular system; the materials which they take up being, in fact, merely the spare nutrient substances forced into the intertextural spaces—that is, the commencement of the lymphatics—by the continued exudation of fresh fluid from the capillaries.[1] The lymphatics never come quite close to the surface of the dermis, but the blood capillaries are superimposed upon them (Teichmann and Belajeff). The lymphatic system consists of vessels, both trunks and capillaries, and of collections of a peculiar kind of connective tissue, adenoid, the meshes of which are crowded with round colourless cells. When these are situated in the course of the lymphatic vessels and are invested with a capsule, they are termed lymphatic glands; but if there is a mere reticulum enclosing the cells, and so forming a patch in the submucous or subserous tissue, it is described as a lymph follicle. Around all such follicles there is a large plexus of lymph capillaries.[2] The principal vessels of the lymphatic system are, in structure and general appearance, like very small and thin-walled veins, and, like them, are provided with valves. By one extremity they commence by fine microscopic branches, the lymphatic capillaries or lymph capillaries, in the organs and tissues of nearly every part of the body; and by their other extremity they end directly or indirectly in two trunks, which open into the large veins near the heart. Their contents pass only in one direction, from the finer branches to the trunks, and so to the large veins, on entering which they are mingled with the stream of blood, and form part of its constituents. The lymphatic capillaries commence most commonly either in closely-meshed networks or in irregular lacunar spaces, between the various structures of which the different organs are compounded. They are composed of a single layer of flattened cells, nearly equal in length and breadth, with a marked sinuous outline. When passing into the large lymphatic vessels they present a varicose appearance, from an incomplete valvular appearance in their interior. In the extremities the lymphatic vessels are divided into superficial and deep. The superficial anastomose freely with one another, and so do the deep, but there is no communication between the two sets, except in the glands, which may be common to both. To this is due the remarkable circumstance that either set may be separately diseased, and that superficial and deep lymphangitis may be spoken of as distinct affections, although inflammation spreads from one group to the other. The mode of anastomosis is peculiar. A lymphatic vessel will run for a certain distance parallel to two other vessels, and then divide; it may join both of them, or one of the branches will continue onwards, and the other run into an adjacent vessel. In this manner a plexus with large meshes is formed. The rapidity with which inflammation spreads from vessel to vessel is thus easily explained.

In certain parts of the body openings exist by which lymphatic capillaries directly communicate with parts hitherto supposed to be closed cavities. These openings have a roundish outline, never exceed the size of an epithelial cell, and have been termed "stomata." An absorption into the lymphatic system also takes place in the membranes covered

by epithelium or endothelium, through the interstitial or intercellular cement substance, and not through the cells themselves. This mode of absorption may be said to take place through pseudo-stomata. Stomata have been found in the pleura; and, as they may be presumed to exist in other serous membranes, it would seem as if the serous cavities, hitherto supposed closed, form part of a large lymph sinus, or widening out, so to speak, of the lymph capillary system, with which they directly communicate.

The current of lymph is much aided by the valvular mechanism. All occasional pressure on the exterior of the lymphatic and lacteal vessels propels the lymph towards the heart. Muscular and other external pressure accelerates the flow of the lymph, as it does that of the blood in the veins. The actions of the muscular fibres of the small intestine, and probably the layer of organic muscle present in each interstitial villus, seem to assist in propelling the chyle. For the general propulsion of the lymph and chyle, it is probable that, together with the *vis a tergo* resulting from absorption and from external pressure, some of the force may be derived from the contractility of the vessels. The respiratory movements also favour the current of lymph through the thoracic duct as they do the current of blood in the thoracic veins.[3]

Blood and lymph are the essential juices of the body. They stand in the closest relation to the vital processes which go on in the tissues. By means of the blood the constituent elements of the body are supplied with the nutrient substances and the oxygen which they require. By the blood and the lymph are conveyed away the waste and surplus matters which have ceased to be useful to the tissues. The nutrient substances and the oxygen are derived from without. The former usually enter the body from the alimentary canal, the latter usually through the lungs. But most parts of the body are, under certain conditions, capable of directly assimilating both nutriment and oxygen. The channels of entrance are in such cases the smaller bloodvessels and lymphatics. The matters which have to be removed from the tissues are partly surplus nutriment, partly the products of tissue waste and metabolism. These matters are carried off either to be utilised elsewhere within the system, or to be ejected altogether. Under normal conditions the incomings and outgoings balance each other in amount. The channels by which the normal constituents gain access to the blood and lymph may also serve to admit matters which are noxious, or at least abnormal. These matters may be either wholly extraneous or produced within the body itself in virtue of some morbid or abnormal metabolism. The result of their admission is a more or less enduring pollution of the blood and lymph. In many cases the blood is able to eliminate them harmlessly and speedily, chiefly by means of the kidneys and the liver, but in other cases the pollution is more permanent. The composition of the blood often suffers in consequence, and its renovation may not be effected until some of the tissues or organs have been more or less injured by malnutrition.[4] The lymph is merely the liquid transuded from the bloodvessels, together with certain products of tissue metabolism and certain matters taken up by the lacteals from the outside. To this the lymphatic glands contribute a number of lymphoid elements, in addition to the few cells derived from the blood. The sources of the lymph being thus somewhat various, it may be expected that morbid changes in the composition will not be uncommon. Changes in the blood and disorders of the tissues generally give rise to changes in the lymph, and the various impurities of the blood are all of them apt to pass into the lymphatic system on leaving the bloodvessels.[5]

With this narration of the anatomy and physiology of the absorbent system, we are in a position to enter upon the disquisition of its pathological relations. The anomalies in the distribution of the lymph will first receive attention. Every change in the circulation which determines an increased transudation of liquid from the blood leads by consequence to an increased saturation of the tissues. This increased saturation is generally balanced by an increased discharge through the lymph channels. But this compensating action has its limits. If the transudation from the bloodvessels still increases, there at last comes a time when the saturation of the tissues with liquid can no longer be kept down, and so it rises above the normal degree. The condition in which fluid collects in the substance of the tissues is called œdema; when in the greater cavities of the body, hydrops or dropsy. The liquid transudation in œdema and dropsy has never the same composition as blood-plasma; it is always markedly poorer in albumen. Three varieties of œdema may be distinguished according to their mode of origin; these are the œdema of engorgement, inflammatory œdema, and hydræmic œdema.

The œdema of engorgement, as the name implies, depends upon a disturbance of the circulation. If from any cause the outflow of blood from the veins is hindered, the blood tends to accumulate in the capillaries and venules. If the degree of obstruction exceeds a certain limit, the plasma seeks a lateral exit and escapes from the vessels. The amount of liquid thus escaping is proportionate to the discrepancy existing between the inflow and the outflow. The escaped liquid is always poor in albumen, poorer even than the normal lymph; it contains, however, a certain proportion of red-blood cells, depending on the intensity of the engorgement. The immediate consequence of increased transudation is an increased flow through the lymphatics. Often enough this may be quite sufficient to convey away all the liquid which escapes. If it is insufficient, the liquid collects in the tissues and the result is œdema or dropsy. Obstruction to the outflow through the lymphatics does not usually bring about œdema; direct experiments have demonstrated this. In the first place, the lymphatics of most parts of the body possess ample anastomoses, so that it is not easy for a stagnation of the lymph to occur. Even when the thoracic duct is occluded, collateral channels may be opened up and the circulation restored. Furthermore, when in a limb, for example, the whole of the lymphatic outlets have been closed, if no more than the normal amount of transudation from the bloodvessels goes on; no œdema is produced. The bloodvessels themselves have the power of taking up again the lymph they have produced. If the thoracic duct be completely occluded and no collaterals are opened up, then œdema is the result; it takes the form of ascites. At the same time the larger lymphatics become greatly distended with accumulated lymph. Though lymphatic engorgement alone is inadequate to produce œdema, it may possibly increase an œdema which has already been produced by increased transudation from the bloodvessels. The quantity and the nature of the liquid which escapes from the capillaries and veins depend not only on the intravascular pressure and the resistance of the flow, but also to a great extent on the character and condition of the vessel wall. Alterations in the amount of transudation may thus be referable, not to disturbance of the circulation, but to changes in the vessel wall, and especially in their endothelial lining. The vessel wall may, in fact, be made more permeable for the corpuscles as well as for the liquid constituents of the blood by various causes; one of these is long-standing engorgement, involving incomplete renewal of the blood-supply to the vessel. More serious causes of injury are persistent ischæmia, imperfect oxygenation, chemical changes in the blood, very high or very low temperatures, and traumatic lesions. What the exact injuries are which these bring about we are not as yet able to say, but it may fairly be imagined that they amount to a loosening of the connexions between the endothelial cells of the intima. It is in virtue of such alterations in the vessels that inflammatory and hydræmic œdema are produced.

As regards inflammatory œdema, no doubt can exist that it originates in some vascular change. It occurs as an independent affection, in the form of a more or less local and circumscribed swelling with dropsical effusion; but it may also, as a secondary phenomenon, accompany other processes, like severe inflammation. In the latter case it is often characterised as collateral œdema. Inflammatory œdema is distinguished from the œdema of engorgement by the fact that in the former the exudation is very much richer in albumen and white blood cells. It is also common for coagulation to take place in the dropsical tissues.

Hydræmic or cachectic œdema is very near akin to inflammatory œdema. It was formerly believed that hydræmia, in which the blood is impoverished of its solid constituents, and hydræmic plethora, or over-dilution of the blood with water, might directly give rise to increased transudation from the vessels. It was conceived that the vessel wall acted like other animal membranes, through which liquids poor in albumen filter more readily than liquids rich in albumen. This is incorrect. Cohnheim has shown that the vessel wall is not to be regarded as a dead membrane, but as a living organ. When hydræmia is artificially produced it

[3] Kirkes' Physiology, p. 362.
[4] Zeigler: Macalister's Translation, part ii., p. 1. [5] Ibid., part ii., p. 33.

Digitized by Google

is not followed by œdema. Even hydræmic plethora produced by over-filling of the vessels with diluted blood, though it leads to increased transudation, does not do so till the dilution has been carried to an extreme degree. Even then the œdema does not make its appearance at the parts which are the usual seat of hydræmic œdema in man. We must therefore look for another explanation of the œdema of cachexia and of nephritis, in which disease the functions of the kidneys is disturbed. According to Cohnheim they owe their origin to a change in the vessel wall. This change is due to the watery character of the blood, or to some deleterious substance circulating in it. Hydræmic œdema is akin to inflammatory œdema, but it is not identical with it. This appears from the fact already alluded to, that the liquid effused in the former is much poorer in albumen than that in the latter, and that it contains considerably fewer of the corpuscular elements.

As to the diffusion of diseases by the lymphatics. The granulative formations are all distinguished by similar characters. Their development usually stops short at the fibro-blast stage, and having reached it, or even before that, the constructive process gives place to retrogressive changes. Cicatricial development being arrested, the granulation tissue persists for a time unmodified, and often develops to a considerable amount. For this reason Virchow described the formations as granulative growths or granulomata. All of these growths have, furthermore, the clinical character of infectiousness. Hence they have been termed "infective growths" by Klebs and Cohnheim, and "specific inflammations" by Rindfleisch. Their infective character may be recognised by various signs. Thus they are all locally invasive—that is, the granulation tissue spreads centrifugally from a centre into the surrounding structures. At the same time the central or oldest part of the new formation usually dies and disintegrates. In many cases the lymphatic system becomes affected, so that secondary granulative foci are formed in it. From the lymphatics the process at times transferred to the blood, or it may invade the blood-vessels directly. The final result is the spread of the disorder to various organs, or throughout the system.

In most of the granulomatous disorders, we may have not merely a diffusion of the disease throughout the individual organism, but also a transference of it from one individual to another. The affection is inoculable. If one person be inoculated with the inflammatory products derived from another, he acquires a disease whose course is exactly similar to that of the original one, and which yields identical inflammatory products. This latter character of infectiousness is that by which it is most readily recognised. To this group of infective granulomata belong the neoplastic formations found in tuberculosis, syphilis, leprosy, lupus, glanders, and actinomycosis. All these affections are due to the invasion of the body by a virus or poison derived from the outer world or from the body of another individual. This virus may probably be produced by vegetable parasites. In leprosy (Hansen, Neisser), tuberculosis (Koch), and syphilis (Klebs), bacteria have been found, and in actinomycosis a special fungus. These are declared to be the originating causes of the respective diseases. Our ideas as to the nature and character of these affections are as yet mainly based upon their clinical course, but we have also derived something from inoculation experiments. Tuberculosis and syphilis are thus known to be communicable from one person to another; tuberculosis is also communicable from man to the lower animals.[7] Inoculation with sputa containing bacilli of tubercle gives rise to tuberculosis, which is developed more rapidly when the bacilli are abundant. The inoculated bacillus multiplies in the organism, and involves the lymphatic system, liver, spleen, and serous membranes; by its presence it sets up a chronic inflammatory process with the formation of products which become caseated, but subsequently soften, producing gradual destruction of the organ. The bacillus is found in the centre of the tubercles in their earliest stage of formation, and hence is the cause and not the effect of the morbid process. The lymphatic vessels, amœboid cells, and the blood current are the means by which these micro-organisms are transported from one organ to another and diffused throughout the body.[8]

(*To be concluded.*)

REMARKS ON THE

COMMUNICABILITY OF PHTHISIS.[1]

By ALFRED G. BARRS, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE LEEDS PUBLIC DISPENSARY.

[DR. BARRS having reviewed in detail the experiments and observations of Buhl, Klencke, Villemin, Marcet, Wilson Fox, Koch, Watson Cheyne, Spina, Cohnheim, Tappeiner, Schottelius, Aufrecht, Weichselbaum, Poulet, and others, proceeded as follows]:—

According to Koch and Watson Cheyne, then, our definition of tubercle in the future is to be by the presence of the tubercle bacillus; and I am not sure that we, who are not mycologists, are in a position to oppose this change. For some years past there has been a general falling away from old morphological or histological definitions in this matter; caseation is gone as a test; the giant-cell has been found in many admittedly non-tubercular substances, such as the syphilitic gumma; and the old intercellular network has been removed by Cornil and Ranvier. Almost all pathologists are prepared to define tubercle, apart from the bacillus, rather by its distribution and tendencies—its life history in short—than by any peculiar structural element. Thus tubercular processes, as we most commonly meet with them in phthisis, constantly show the bacillus in greater or less quantity, I have no doubt; I have myself found it in all the cases of phthisis (thirty in number) which have come under my observation during the last year, and the number of cases on record in which others have found it now far exceeds five hundred. Of negative observers upon this point, I shall refer to one only, who, if he still adheres to his original position in regard to the bacillus, stands almost alone. I need scarcely say I refer to Spina, of Vienna, who, with great energy and some feeling, took up every point in Koch's paper, and produced arguments and experiments to refute them. He denied the characteristic reactions of the bacillus, and that they were found in tubercular matter only, and adduced many other points which have needed confirmation from the time they were published (1883) to the present. In short, the constant presence of the bacillus in tubercular tissue has been affirmed by all who have taken the trouble to look for it, and in no other substance has it been found.

Time does not permit me to enter into any discussion of the relations of tubercle to phthisis. Were I to propound a view which I held almost up to the time of collecting the materials for this paper, I should, I doubt not, be accounted one of a bygone age. The simple broncho-pneumonic theory, as propounded by Niemeyer, now nearly twenty years ago, and twenty years before that by Addison, had always seemed to me one which could be embraced without doing violence to one's reason or to clinical and pathological facts. Indeed, when tubercle was looked upon as clinically malignant, one saw no other way of explaining the cases of recovery which one was now and again obliged to admit, as well as the large number of cases which used to be designated, and, as it seems to me, rightly so, mechanical phthisis; but the discovery of the bacillus has changed all this. When in every case of phthisis an organism is found which is common to it and all other manifestations of tubercle in the human subject, and also in all animals subject to the disease, spontaneously or artificially produced, one cannot but abandon, though with much regret, the dualistic theory; in fact, I believe the unity of pulmonary phthisis is now almost universally admitted.

As to the positive evidence of contagion in the human subject, there is little forthcoming, and that little is of a very doubtful nature. In this country the only extensive investigation made in this direction was made by the Collective Investigation Committee last year. Prior to this the only cases on record are those previously referred to, published by Dr. Hermann Weber and Villemin. The Collective Investigation Committee, as will be remembered, issued to the members of the British Medical Association, on two occasions inquiries as to the communicability of phthisis. Of the 10,000 or more members, only 1028 replied; of these, 673 had seen no examples, 261 reported cases they

[1] Being the concluding portions of a paper read at the opening of a debate on the Communicability of Phthisis, at the meeting of the Leeds and West Riding Medico-Chirurgical Society, March 7th, 1884.

Digitized by Google

believed to support the infective theory, and the remainder were doubtful or negative.

I propose to criticise with some minuteness Dr. Hermann Weber's cases of supposed transmission from husband to wife. I do this because they are the most fully reported cases with which I am acquainted, and because they are not infrequently quoted by the complete believers in communicability as providing almost all that is to be desired in the way of evidence in favour of their views. The cases are nine in number, and are reported in the Transactions of the Clinical Society for 1874, though they seem to have occurred some years previous to that time. The husband is in every instance described as of consumptive family; they all (the husbands) suffered from hæmoptysis between their eighteenth and twenty-first years; and they all survived, save one, a second marriage at least; and one survived a fourth, and another a third. The marriages, too, were not repeated with absolutely indecent haste, consequently the husbands survived for some considerable period in each case the first marriage, in which they are supposed to have transmitted phthisis to their partners. They are all described as healthy, or considered so, at the time of marriage; and they all, save one, died of phthisis, as stated by their medical attendants or as ascertained by post-mortem examination. Amongst the many remarkable points in these cases, the most noteworthy to me is the period of time which elapsed between the supposed infection of the first wife, when of course the husband was regarded as suffering from phthisis, and his death. In Case 1 the period I have calculated from the facts given was at least twenty-five years, in Case 3 nine years, in Case 4 twelve, in Case 6 eight, in Case 7 eight, and in Case 8 ten; in the remaining cases no definite figures are given, but calculating from the number of pregnancies of the wives and other statements it may be roughly stated at from five to nine years. The man in Case 9 married his first wife in 1867, his second in 1868, and was living and well in 1872. To return to Case 1. A man said to be of marked phthisical family, to have had hæmoptysis at twenty-one, and to have infected four successive wives with consumption, lives through twenty-five years to tell the tale. Can this seriously be taken as an example of infection from husband to wife? Suppose him to have been perfectly well, as stated, at twenty-seven, when he married his first wife, who showed symptoms of phthisis after the third pregnancy—that is, four years after marriage at the earliest,—and take this as the commencement of his own disease; after an interval of ten years he marries his second wife, whom he infects; the intervals between the second and third and third and fourth are not given, but say the time allowed to elapse between the death of one wife and the marriage of another was twelve months; this, added to the time which each wife lived, will give us a period of not less than seven years, during which period he must have been exhaling the contagium of phthisis, or, in other words, have been suffering from active lung disease, and then survived the last of his supposed victims for eleven years, when he died and presented the following changes in the lungs: "a cicatrised condition of the former seat of disease, and also the recent affection." I confess I do not see my way to accepting in any sense this case as proof of direct infection from husband to wife; rather it is to me a more than gratifying example of the curability of phthisis, and a proof that a man may cohabit with four individuals dying of consumption, who is himself of consumptive extraction, who has exhibited lung symptoms from his twenty-first to his twenty-fifth year, and lives to the not unripe age of fifty-seven, having expressed some doubts as to the propriety of even a fifth marriage.

This line of criticism, which I deem not unfair, may be applied with the same result to all Dr. Weber's cases. They prove too much, not only of contagion, but of recovery from what we regard as a commonly lethal condition. The cases published in abstract in the Collective Investigation Record scarcely admit of analysis, the statements being in so many cases simply the conclusions of the reporters, and not the facts upon which the conclusions are based. In Dr. Weber's cases, and also in the collective investigation cases, I beg you to notice the entire absence of cases of acute general tuberculosis, of tubercular meningitis, strumous arthritis, and of urino-genitary tuberculosis, all of which diseases are to be accounted manifestations of tubercular affection in the human subject, and cases of which we have a right to expect if the theory be true as applied to man in these so-called examples of infection.

To proceed further with the negative side of the question. I need scarcely refer to the very striking statistics of the Brompton Hospital in regard to the affection of attendants resident in the hospital. During the last twenty-five years not a single case of phthisis fairly traceable to the surroundings could be found amongst more than 250 officials connected with the hospital during that time. The mortality, in fact, amongst residents was lower than in some general hospitals. It has been said that this proves only that under such conditions as exist at Brompton phthisis is not contagious, and that it cannot be taken as in any degree settling the whole question. But, I would ask, do the conditions at Brompton differ in kind or even in degree from the condition under which life will go on amongst us? The element for contagion has been shown to exist in the atmosphere of the building generally, and Dr. Charnley Smith has shown also that the bacillus is continually escaping from the air-passages of phthisical patients.

My own conclusions upon this extremely wide and difficult question are, I need scarcely say, subject to revision. In the main they are as follows:—1. The tubercle bacillus is constantly found in all lesions of a tubercular nature, and in all cases of pulmonary phthisis in the human subject. 2. So far as the communicability of tuberculosis in animals is concerned, this is clearly proved by inoculation experiments. Whether it is so without antecedent traumatism there is very little evidence to show. 3. The great prevalence of phthisis amongst those of certain occupations, and the comparative rarity with which those presenting caseous changes in the lungs die by means of a general infection, tend to show that certain predisposing causes are necessary for the production of phthisis—some more definite condition than a mere obliquity of construction, such as we mean by constitutional tendency. The bacillus is not in this case the real and primary cause of the disease, but by its constant presence may determine a wide distribution of the lesion and a fatal result. 3. Although the discovery and isolation of Koch's bacillus and the inoculation experiments upon animals make the direct infection of individuals with tuberculous matter possible under certain conditions, these conditions are not established by our present mode of life. 4. The clinical evidence of direct infection from man to man is at present of a quite untrustworthy nature. I need scarcely add that the want of proof of direct contagion in no way militates against the view that pulmonary phthisis is an infectious disorder—that is, due to the introduction of an infective particle from without.

SOME

STATISTICS AND OBSERVATIONS REGARDING LITHOTOMY IN THE HYDERABAD CIVIL HOSPITAL, SINDH.

By SURGEON-MAJOR B. C. KEELAN, L.M.D.,

ACTING CIVIL SURGEON, HYDERABAD, AND SUPERINTENDENT OF THE HYDERABAD MEDICAL SCHOOL; CIVIL SURGEON, DHULIA, BOMBAY PRESIDENCY.

TABLE I. is a summary taken from the monthly returns of the above hospital of the operations for lithotomy performed by myself from the 1st January, 1883, to the 31st August, 1883, a period of eight months. It gives the number of cases, with the ages, results of the operation, &c. The patients were all in good health, with the exception of the symptoms arising from stone in the bladder. Of the 102 cases operated upon, 81 were Mussulmans and 21 were Hindoos, of whom 98 were males and 4 were females. To avoid taking up too much space, I have been obliged to arrange their ages into quinquennial periods. The table will show that Sindees are infinitely better subjects for operation than Europeans, being so much less liable to inflammation setting in after the operation, owing probably to the simple manner in which they live, and perhaps to the very dry climate of Hyderabad. The operations at the other hospitals in Sindh, though fewer, have reached to pretty nearly about the same favourable results; consequently lithotomy here in Sindh is not looked upon as a formidable procedure, as is the case in Europe, owing to the mortality being comparatively so very low. The table will also show the average number of days spent in hospital, as well as the average duration of the formation of calculi, arranged in quinquennial periods, to correspond with the ages of persons

Digitized by Google

operated upon; the weights of the stones are arranged in the same manner for the purpose of condensing information.

It will be seen from the statistics that stone in this country is more prevalent in children from one to ten, and in adults from thirty-one to fifty, years of age than at any other time of life; during this latter period of life also calculi are larger, taking the average; this is remarkable, but is nevertheless the case. My object in publishing these statistics is to point out the superiority of lithotomy as an operation over that of lithotrity, and also to show a cursory outline of the method of operating upon, and of treating calculus in the bladder as carried out in the Civil Hospital of Hyderabad, Sindh, which is considerably the largest hospital for lithotomy in India.

It may be interesting to the profession in England to mention that stone in the bladder is exceedingly common all over Sindh, a district in the Bombay Presidency about as large as England and Wales. Through the middle of this tract of land passes the mighty river Indus, which takes its origin from the melting snow of the far-off Hindoo Khoush Mountains, and courses down through the Punjaub and Sindh, falling into the Indian Ocean south of Karachi. Indeed, I think I may say without fear of contradiction, that calculus in the bladder is much more prevalent in Sindh than in any other part of the world. It appears to be hereditary, and in my opinion it also arises from drinking the muddy water of the river Indus and its tributaries, which the natives of this country invariably do without filtering it, or even allowing to settle to the bottom of their vessels the silt which is suspended in it so abundantly as to render it quite thick and of a brownish colour; however, the addition of a few grains of alum makes it clear and sparkling; but the natives, though many of them are aware of this fact, seldom trouble themselves about it. Again, Sindh is probably one of the most dusty countries in the world, especially lower Sindh, so that the native inhabitants (Sindees) may truly be said to be continually eating and drinking fine particles of earth. I imagine there can be no doubt whatever but that this alluvial matter, all of which is carried down by the Indus, is the fountain head to which the origin of stone in the bladder can be traced in this part of India, and that the silt brought down by the river from its source supplies to the urine the earthy materials from which the calculi are formed in the bladder.

Table II. shows the number of patients operated upon who were able to trace their own disease (calculi) in one or more members of their family, including also their cousin relationship; it also shows the kinds of stones operated upon, as well as the quality of the water used for cooking and for drinking purposes. It will be seen that no less than 90 per cent. of the persons operated upon used for all purposes the muddy river water; nearly 23 per cent. may be said to have been hereditary; and nearly 70 per cent. of the stones operated upon were phosphate of lime. Professor Gamgee states that the sheep in the hill districts of Wales get stone in the bladder from feeding on the short grass, which is covered with dust, and which is peculiar to the sheep hills of that country; and I see no reason whatever to suppose that the prevalence of stone in Sindh may not be attributable to the same source. Professor Gamgee's statement no doubt applies to Sindh and the Sindees.

Table III. gives the number of stones extracted in each of the 102 cases of lithotomy under review, the number of cases previously operated upon, and the interval between the first and second operation, also the weights of the secondary

stones. All the secondary stones were composed of phosphate of lime.

From observation of several hundred cases of lithotomy, I find that it takes on an average about two years and a half for a stone weighing, say, two ounces to form—that is, of course, counting from the time the symptoms begin to be observed by the patient; a stone of five ounces will take seven or eight years to form. Small stones weighing only two drachms in the bladder of an adult, provided always that they be smooth on the surface, will cause very little inconvenience or suffering, and adults rarely apply for relief when the stones have only reached this stage of development. I have frequently operated on the same patient twice in from four to six years, each time the stone weighing from two to nearly three ounces. The lateral operation is the one invariably performed in the Hyderabad Hospital. The calculus is reached in the usual way; if it be small there is never any difficulty, but if large its successful removal can only be accomplished by long practice. In removing a large stone, it should not be taken out of the bladder with any degree of force, nor should pulling be resorted to, lest the neck of the bladder be contused and lacerated; of all others, this is the chief point to be attended to in lithotomy, for any departure from this, which should be considered a golden rule, would be the cause of immense mortality—a fact which is experienced by young operators, and which I have had experience of myself as a beginner. Before applying the forceps to the stone, the forefinger of the left hand is passed through the wound on to the stone, the size of which is ascertained, then a blunt pointed knife is passed along the finger, and the neck of the bladder incised according to the size of the stone; the wound is also enlarged proportionately; then, having applied the forceps, the stone is pulled in the proper direction, and at the same time rocked a little from side to side and from above downwards; this has to be very gently done. If the stone does not come then, the forceps is given to an assistant to hold, and the index-finger of the left hand is inserted into the wound, which is searched in every direction, and that part of it which is put on the stretch, by the pressure of the stone against it, is cut pretty freely in as many places as the circumstances of the particular case will demand. It matters not whether it be above, below, or to the right or left side; the soft parts must be cut in all directions, if necessary, rather than use force. Then the forceps is again taken from the assistant, and the stone gently pulled and rocked as before; it is on this procedure that the success of the operation for extracting a large-sized stone entirely depends, and the cutting process just described is repeated as often as necessary. Hæmorrhage is exceedingly rare, and is easily restrained. I have only seen three or four instances of severe bleeding amongst hundreds of cases, and these were soon arrested. After the operation the patient is placed on his side, the thighs being brought very close together; a compress of very fine tow (called by us in India "surgeon's tow,") is placed on the wound, and held there tightly by an assistant for half an hour or longer if necessary. This is the very best way I know of compassing the stoppage of hæmorrhage; it is very simple, no styptics being required, for these often do harm by irritating the bladder, and it is a great mistake to suppose that bleeding will take place into the bladder when the wound is pressed externally. Plugging the wound round a catheter should be avoided; it is most objectionable and hurtful to the patient. In the after-treatment no catheter is required to be placed in the wound; it does not answer, as it keeps up irritation of the bladder—the very thing, of all others, to be avoided after the operation. It is better that the urine should pass through the wound unaided, unless it happens to be stopped momentarily by clots of blood, and then it is sufficient merely to pass a straight silver tube, just to clear the passage for the urine to flow, and then withdraw it immediately. It is not very often that clots impede the passage of urine, and only when this occurs should a tube be passed through.

Hyderabad, Sindh.

THEFTS FROM MEDICAL MEN.—A young man was recently charged at Liverpool Police-court with a long series of thefts from the houses of medical men, committed whilst he was ostensibly waiting the return home of the doctor. The property stolen from over twenty members of the profession in Liverpool, Birkenhead, and Manchester, included many surgical instruments, a galvanic battery, and various articles of clothing. The prisoner was committed for trial.

ON FIVE CASES OF

SPORADIC CRETINISM IN SCOTLAND.

BY ROBERT KIRK, M.D., F.F.P.S. GLASG.,
OUT-DOOR PHYSICIAN-ACCOUCHEUR TO THE GLASGOW WESTERN INFIRMARY.

SPORADIC CRETINISM is not only interesting from its rarity, but has acquired an unusually high degree of importance of late from its probable affinity to myxœdema in adults. The following account of five cases I have lately met with, of which two are represented by woodcuts, will therefore be read with interest.

CASE 1.—G. B——, a boy aged twelve years (Fig. 1). I encountered this case accidentally in my daily rounds, and was at once struck with the close resemblance he presented to the only case of myxœdema I had previously seen, that of a female aged fifty-six, and which I showed to the Medico-Chirurgical Society of Glasgow last winter. The boy was enormously swollen, and judging from his height, seemed only three years old, although I was told he had reached the age of twelve. On inquiry, the following particulars were elicited. His parents belong to the village of Ladybank, in Fifeshire, where I afterwards met with Case 2. They are both healthy and well developed, above the average height (the father being six feet high), not related to each other,

FIG. 1.

free from goitre, and of strictly sober habits, the father never having been intoxicated in his life. There is no history on either side of goitre, intermarriage of relatives, intemperance, or tendency to any hereditary disease. The boy is the fifth of six children, all of whom are well except himself. During gestation his mother felt ill, took little food, and vomited much. She had severe pains or cramps in the abdomen almost daily; these often compelled her to get out of bed at night and sit by the fire for hours together. When the infant was born he was large and stout, and, as the mother supposed, an unusually fine child; he was at least half as heavy again as any of her other children at birth. She soon observed, however, that he was very sluggish; he always leant forwards in her arms, and he slept a great deal; he seldom cried, and did not smile like other children; his skin was always cold. He did not grow taller; did not walk till he was five years old, and then with a feeble, tottering step, the slightest obstacle overturning him; he did not get all his teeth till seven, when also he first made some rude attempts at speech. He had become much stouter during the last two years. He is now three feet in height, and weighs 4 st. 1 lb. He measures round the head 20½ in., round the abdomen 29 in., and round the thigh 16 in. His legs and arms are short; he is extremely broad in proportion to his height; buttoned in his coat, which reaches below his knees, he is like a barrel, and is, in fact, a marked example of myxœdema. The face is as broad as it is long, dull, and expressionless; ears thick and doughy; lips thick; hands short, swollen, and clumsy; ab-

Digitized by Google

domen very protuberant, communicating a feeling of resistance and solidity on pressure; eyelids puffy; neck short and thick; skin hanging in large folds from the lower jaw. The supra-clavicular swellings, described by Mr. Curling and Dr. Fagge, are well marked on either side; they are soft and inelastic, but do not seem capable of being drawn down over the clavicle; they are not well-defined, but merge gradually into the surrounding swollen integument; the folds of skin hanging from the jaw rest on them, so that the neck presents a deep transverse fissure. The outline of the trachea can be distinctly traced by the fingers, apparently indicating the absence of the thyroid body; but, desirous of having further evidence on this important point I requested Dr. H. C. Cameron, surgeon to the Western Infirmary, to examine the case; he kindly did so, and came to the conclusion that the thyroid body was entirely absent. The nose is small and somewhat flat; depressed at the root, and slightly turned up at the point; the alæ nasi are but little expanded, and the interval between the eyes is not abnormally great. The forehead is somewhat narrow, and the head round; the anterior fontanelle is not yet closed, and the bilateral diameter of the head seems large in proportion to that of the antero-posterior. It appears to be the same with the trunk, the back being very broad and flat; there is a slight anterior curvature of the spine (lordosis) in the lumbar region, and the tibiæ are slightly bent at their lower part. The skin is rather sallow, but has a tolerably healthy appearance, and is not translucent; the cheeks are a little ruddy, but do not show the pink spots of adult myxœdema; the exposed parts of the skin are cold to the touch; the backs of the hands are wrinkled, but in most parts the skin is smooth and soft, and nowhere shows any tendency to furfuraceous desquamation. Dr. Ord has remarked[1] that we do not find in the report of the Sardinian Commission on Cretinism that a general dryness, harshness, and coarseness of skin prevails among cretins as in adult subjects of myxœdema, and it is interesting to remark that my patient conforms to the description of the former, and not the latter. Nevertheless, I observed that if the surface of the skin in some parts, as over the loins and the lower limbs, was gently grazed with the fingers or the palm of the hand, a sharp grating sensation was felt, like that communicated by sandpaper. He never sweats, and the secretion of sebaceous matter seems to be arrested. The hair of the scalp is very scanty and scattered; it is harsh, dry, and brittle, and the skin scurfy, amounting to pityriasis capitis. The eyebrows are rather thin and slightly oblique, eyelashes long, thin on the lower lids, which are red and inflamed. His nails are very thin and brittle. He has all his first set of teeth, although the back ones have partly decayed; the front ones are blackish and very small, leaving a free space between each. The tongue is thick and dry; the hard palate not much arched. The pulse is 76, weak; respiration short and quick (32), often accompanied by a slight snuffle, or rather snort; temperature in the axilla on three occasions, 97°, 97·8°, and 97·6°. He likes the fire in cold weather, but does not quickly feel changes of temperature. He eats and drinks very little; sleeps regularly twelve hours out of the twenty-four, snoring loudly. His urine averages 10 oz. in the twenty-four hours; feebly acid, sp. gr. 1025, free from anything abnormal; I have not yet made any estimation of the daily excretion of urea. All his movements are extremely slow. He walks with a balancing gait, the legs being wide apart, and is still very easily knocked over. His intonation is strongly nasal, his speech confined to single words for the most part, and he frequently omits consonants. His parents have never attempted to teach him the alphabet, and he cannot count ten. He is very quiet and docile, and has no mischievous propensities. His senses seem all good, and he feels a pinch or scratch acutely. He is fond of music, and can even hum a tune. He sometimes laughs heartily, and frequently he relaxes into a smile; when he does so the swollen eyelids close altogether, and I have been struck with the identical expression which he then assumes to the case of adult myxœdema already mentioned.

CASE 2.—A. D——, aged eleven years, also a boy (Fig. 2), was born in the village of Ladybank, above mentioned, the native place of both his parents. The family history is the same as in the preceding case, with the important exception that the mother has a goitre larger than the fist on the right side of the neck, which began to appear, she says, shortly after she was married. Her mother had a small hard swelling the size of a marble on the front of her neck. Of six maternal aunts, two (both unmarried) had large goitres, one of them extending quite across the neck. These are all the instances of bronchocele she knows of amongst her ancestors, and there were none in her husband's family. The child in question is the fifth of nine, and was born when the mother was thirty-three; all her other children are well. During pregnancy there was nothing unusual in her state of health, except that she felt weak and disposed to rest during the latter part of it. She suffered severely in labour, but was delivered without forceps. The child at his birth was short and thick, especially over the belly; she is sure he was much heavier than any of her other children. He had long, dark, curly hair, extending even over his back, but this was all shed before he was a few months old. All the rest of her children were fair, and had light hair, which at first was both scanty and short, but gradually grew. His skin was very dark, and his lips blue, sometimes intensely so; his entire body was cold: these peculiarities have continued ever since. He slept a great deal, and, in short, progressed like Case 1 in every respect. He has never had any ailment, although he has slept in the same bed with cases of measles and whooping-cough. He is now 2 ft. 7 in. in height, and weighs 2 st. 9 lb. He measures round the head 21 in., and round the abdomen 24 in. His legs and arms are short, and not very thick; head massive; trunk voluminous in proportion to his height; neck extremely short, the head being set

FIG. 2.

almost directly on the shoulders. He is of a more pronounced cretinous type of conformation than G. B——, although by no means such a well-marked example of myxœdema; the broad, squat build thus appearing to be dependent on the skeleton, and not on any growth of soft tissue. His head is long, as well as broad; anterior fontanelle not yet closed; forehead high and broad; face broad and flat, though not much swollen; mouth large and wide, and lips thick; nose flattened at the root, markedly elevated at the point; alæ nasi more flattened and curved than in G. B——; wider interval between the eyes; eyebrows more oblique. The trunk is bulky, and the bilateral diameter great in proportion to the antero-posterior, making the back broad and flat; some degree of lordosis of the spine in the lumbar region; tibiæ bent at their lower part. The soft parts of the body are not much swollen; the ribs are very distinctly seen, and even the outline of the abdominal muscles is visible to the eye. The supra-clavicular eminences are but slightly marked; indeed, they can scarcely be said to exist, but his mother expressly states that he often swells considerably in their situation, especially on exertion. I could detect no trace of a thyroid body, but he made the examination difficult by a sturdy resistance. His skin is cold; it is dark, sallow, and dry, and has a leathery appearance; in many parts, as the scalp, it is wrinkled, and can be pinched up into large folds, as in advanced cases of adult myxœdema. The scalp, hair, and nails resemble those of Case 1; there is no furfuraceous shedding of epithelium. There is no translucency of the skin anywhere, and no pink flush on the

[1] Med. Chirurg. Soc. Trans., vol. lxi., p. 70.

Digitized by Google

cheeks. He does not sweat. The skin feels like sand-paper when gently rubbed; it is thickest over the back of the neck, the belly, scrotum, and thighs, which are probably the seats of some amount of myxœdema. He has only a few teeth in front, which are small and discrete, as in G B——; the back ones have been lost by decay; he never shed any, and has got none of the permanent set. The tongue is broad and thick, dry, and leathery; the palate narrow and highly arched. His gait is a feeble, waddling totter, with the legs widely apart, as if in momentary expectation of falling. His speech is inferior to that of Case 1, and he is slower in his movements. He is in some respects livelier, however; he frequently laughs, and has a considerable sense of humour; he also resents interference more, and cries lustily. He is not vicious, and behaves very well in church. All his senses are good, and he is said to be fond of music, although he cannot reproduce any musical note. He takes very little food, and sleeps much; his circulation is very feeble; respiration not hurried, as in Case 1 (this, I believe, being due to the myxœdema in the latter); temperature in the axilla, 97 6°. Through the mother of this patient I learned of the existence of the following three cases.

CASE 3.—G. R. H——, a boy, aged ten years and a half, living in the town of Perth. The family history in this case is the same as in Case 1. The boy was the first of four children, all of whom are well except himself. During pregnancy his mother had the best of health, but during the latter part of it she had frequent occasion to see a dwarf (whom, she says, her boy now resembles, and who, indeed, seems to have been a cretin), but she attached no importance to the circumstance. About the eighth month she had a fall, and afterwards she supposed the child was dead, as movement nearly ceased. He was born apparently lifeless, but the doctor succeeded in resuscitating him; he was a feeble infant, and was both short and thin; his legs and arms, besides being thin, were short in proportion to his body. His history from infancy onwards has been much the same as in the former two cases, except that he was not so slow in any respect, that he never swelled, that he did not sleep more than usual, and that he has two lower incisors of the permanent teeth. He can read a few words, but his father remarked that it was vain to send him to school. His height is 2 ft. 11 in.; his weight has not been ascertained, but on lifting him he feels very heavy and solid. He measures round the head 20¾ in., and round the abdomen 23½ in. The occiput projects backwards, making the head look very long; the arms and legs are very short in proportion to the trunk, which is not so broad as in the previous two cases; neck thin, and not very short; abdomen tumid, soft, and yielding. He seems muscular about the limbs; the muscles of the calf, thigh, and arms are very prominent; the pectorals are not in proportion. His face is not too broad in proportion to its length, but the lips are thick, especially the lower, and there is a wider interval between the eyes than in Case 2; nose markedly depressed at the root, and a little upturned at the point; cheeks a little puffy and flaccid. The tongue is moist, and not too large. The two permanent incisors above mentioned have each two marked perpendicular notches, thus presenting three points along their edges. The ears are a little doughy, but not thick; the hands sallow and wrinkled; neck thin; lower part of the larynx pretty close to the sternum. The thyroid could be felt, as I supposed, on the right and over the isthmus, but not on the left; no trace of supra-clavicular swellings; no folds hanging from the jaw. He is somewhat fair and freckled, but sallow compared with his brothers and sisters; hair coarse, dry, and somewhat scanty. The skin feels cool, and there is free desquamation of fine cuticular scales at all parts; this is very visible to the eye, and when his shirt is taken off a fine shower falls, which, his mother says, is of daily occurrence. Nevertheless, the skin is everywhere soft, and communicates no sand-paper feeling to the fingers; veins are visible all over the surface, especially over the abdomen. His nails are brittle; the front edges of the finger-nails curve forwards at a right angle to the posterior part; the nails of the great toe are traversed by several transverse markings. He walks very well, and with a short, decided step. He speaks pretty well, but his intonation is markedly nasal. He can write figures and letters on a slate, and can read a little. All his senses are good. His circulation and respiration are feeble; temperature 98·2°. He is extremely sensitive to cold, and fond of the fire. He never sweats except in hot weather, and he takes very little food. His parents are not aware whether he can recognise colours, of which his vocabulary does not include the names; though he is said to have a retentive memory in some things, and to be very observant.

(To be concluded.)

ALIBERT'S CHELOID (?) FROM INDIA.

BY A. ST. CLAIR BUXTON, F.R.C.S.

MR. J. Y. D——, a gentleman in the prime of life, presented himself to me in January for surgical assistance. He told me he had lived in India for several years, and had always enjoyed good general health. About two years ago some small boils (not Delhi boils, which are probably parasitic) made their appearance in various regions, some on the shin of one leg. In due course they went through the usual stages, and eventually nothing remained except a sense of soreness about the seat of those on the shin. This soreness continued, and although the skin was not acutely inflamed nor broken, an elevation was after a while noticed at one of the tender points; it was pale and flattened, and it increased by spreading in each direction (without rising much), but more in the direction of the axis of the limb than laterally. Another of the points took on the same action, and yet another. These were all situated about the junction of the middle and upper third of the leg on its anterior aspect, the largest being over the internal surface of the tibia, the others over the tibialis anticus. Meanwhile medical aid was had recourse to, and dilute nitrate of mercury ointment was applied, but without much benefit. Then iodine was tried, with the result of lessening the dimensions of the patches to some extent. As little or no inconvenience, beyond occasional irritation, was felt, the treatment became somewhat neglected. About this time Mr. D—— accidentally scraped his shin, by missing his footing, against the sharp iron step of a railway-carriage, and the edge of the metal plate roughly tore away one of the large patches. After the abrasion had healed, it was observed that the cicatrix was thickening and beginning to spread. He then came to England, and it was at this period that I saw him.

Careful examination revealed three islands of elevated tissue, two of which had nearly coalesced, the third being quite separate. They were all more or less of an elongated oval form, raised about the eighth of an inch, or rather more, above the level of the surrounding skin; pale, smooth, and dense, with hair growing sparsely in, though abundantly around, them; and each having a dull bluish tint along the borders. Pressure with the finger produced little or no indentation, but some pain. Two or three groups of suspicious-looking purplish spots, each about the size of a sixpence, were scattered about the leg. These faded somewhat on pressure. A few days later some of them broke down into a state of ulceration, and ran together; these were over the front of the ankle, and on the lowest third of the leg. The others remained passive awhile, and then slowly disappeared. Probably a high-laced boot was answerable for these ulcerations.

The family history of the patient proved no inheritance of syphilis, nor had the disease ever been contracted. The other leg had always remained sound, and the original boils had healed up in the other parts of the body; indeed, all trace of them had vanished. Dust and sand might have contributed something to the perversion of the cell growth now under consideration. Free perspiration would, it is conceivable, cause much foreign material to adhere in a fine state of division to the lower extremities, and this would be rubbed into the surface of the skin by the clothes, and produce considerable irritation in tender spots. My diagnosis was "perverted cell growth in the cutis vera," and for want of a better name I called it "cheloid."

I suggested an absorbent plan of treatment for the elevations, and I healed up the raw surface with lead lotion. The absorbents, however, appeared not to have the slightest effect on the patches, and I then proposed to my patient that we should seek the assistance of Sir Joseph Fayrer, to which he readily assented. Sir Joseph went most carefully into the details of the history of the case, and finally agreed that the tumours were the products of perverted cell-growth in the cutis vera, but would not pledge himself as to their being cheloid. As absorbents had failed, it was deemed desirable

Digitized by Google

that an attempt at radical cure should be made at once. Sir Joseph thought it was within the bounds of possibility that a growth of this type might take on a malignant tendency if subjected in a hot climate to continued irritation. The course he advised was steady blistering until complete destruction of all epithelial tissue had taken place both at the seat of trouble and well round it, keeping the sore open and active by the application of savin. This plan of treatment I carried out fully, and produced a couple of large deep ulcers, the two patches which were so near together being treated as one. I kept the sores open for nearly three weeks, and then allowed them gradually to heal, dressing them with carbolised oil (1 in 20). The carbolic acid was well borne, and I had the satisfaction of finding the resulting cicatrix firm and flat. The last dressing was applied on March 5th, and since that date Mr. D—— has had no symptoms of any return of his trouble. Perfect rest in the horizontal position, with the leg well up, was maintained throughout.

Orchard-street, Portman-square, W.

CASE OF SACCULATED ANEURYSM OF THE DESCENDING THORACIC AORTA OPENING INTO THE LEFT BRONCHUS.

By C. D'A. COLLINGS, M.A., M.B. OXON.

THE following case is interesting from the rarity of similar aneurysms in women, and from the difficulty of arriving at a correct diagnosis before the bursting of the sac into the air-passages.

Maria C——, aged forty-eight, a Frenchwoman, of intemperate habits, but without any distinct syphilitic history, was admitted into the hospital on April 26th, suffering from dyspnœa. She carried on her trade as a hawker until two or three days previously, when, the difficulty of breathing having increased, she took to her bed.

On admission her temperature was 103·5°, pulse 120, and respiration 55; lips and nails livid; respiration somewhat wheezing; expectoration tolerably copious and frothy, with only a very slight rusty tinge. Examination of the chest revealed dulness all over the left side, both in front and behind; heart's apex not displaced. Measurement of left side of chest at level of fifth cartilage, 16¼ in.; of right side, 16 in. Bronchial breathing was heard in the left infra-clavicular and over the left scapular regions; over the rest of the left side the respiratory murmur was greatly diminished, but somewhat bronchial in character, expiration being more audible than inspiration; there was slight bronchophony in the left scapular region. The heart sounds were normal; no murmur was heard either in front of the chest or behind. Radial pulses and pupils equal.

The elevation of temperature continued for about fifteen days, when it gradually subsided to normal; the duskiness disappeared; the respiration was reduced to about 20, and the pulse to 80. The physical signs remained unaltered, but the heart's apex beat was displaced somewhat outwards and upwards, being felt about half an inch external to and in the nipple line. The patient was feeling much easier, and was allowed to get up a little each day; she still complained of some pain referred to the lower angle of the left scapula and down the left arm. Some blood-stained serum was drawn from the pleural cavity by a hypodermic syringe; but a day or two later no fluid could be drawn off by the aspirator. On the morning of May 27th the patient got up to have her bed made, and on getting into bed again was seized with a fit of coughing, bringing up about two pints of bright-red blood, which poured from the mouth and nose. When seen five minutes later she was found to be quite dead.

Necropsy.—On opening the thorax, the right lung was found to be quite healthy, but enlarged, encroaching over to the left side. The left lung was found collapsed and utterly airless, the pleural cavity containing about half a pint of fluid. The heart was normal; there was no valvular disease or hypertrophy. The whole of the arch of the aorta was found to be atheromatous, only small patches remaining of normal appearance. On the anterior part of the descending aorta, as it lay behind the left bronchus, was found a saccular aneurysm, about the size of a horse chesnut, lined with laminated fibrin, the opening into the aorta being about the size of a threepenny-piece. There was an opening from it into the bronchus about the size of a quill; the sac and part of the bronchus extending to the trachea were filled with clot; the distal part of the bronchus contained no clot, but only blood-stained mucus. There was very little induration of the tissues around the sac. Liver and other organs normal.

Guernsey.

TWO CASES OF RUPTURE OF THE HEART.

By A. WITHERS GREEN, M.R.C.S., L.R.C.P.

CASE 1.—E. T. H——, aged seventy-seven, a heavy man, went to bed as usual one night in October, 1881. On the servant bringing him in his breakfast next morning, he found him dead in his bed. The deceased was known to be somewhat eccentric; he was said to be subject to fits of some kind, and to have had rheumatism in 1878. He was a revising barrister. A post-mortem examination showed the brain and lungs to be healthy. The heart was dilated and flabby, the aortic valves containing some chalky deposit. The right coronary artery was thickened, and felt like a cord from outside. On stripping it up from the aorta, a recent but ante-mortem clot, an inch long, was reached, and beyond it a much older, tough, adherent clot; further on still was an extravasation of blood through the posterior wall of the right ventricle. There was blood between the muscle of the heart and the visceral layer of the pericardium, and a pint of blood, half of which was clotted, in the pericardial sac. It would seem that the atheroma in the right coronary artery had led to almost complete plugging of the artery, but it was the fresh clot completely occluding the artery which probably caused the rupture.

CASE 2.—W. J. H. W——, aged sixty-six, a well-made man, on May 7th was sitting listening to a debate, as was his wont, in which he never took any part. Suddenly he fell off his seat, was laid flat on the ground by those nearest him, gave a few deep inspirations, and expired. The deceased was a retired engraver, and was believed to have lived a steady life. Three days before his death he complained of pain at his left side, but would see no doctor. At the time of his death he was drinking gin, instead of his usual beverage of malt liquor. On post-mortem examination, the left pupil was found to be dilated, and the muscles of the left side of the face appeared as in facial paralysis. The vessels at the base of the brain were very atheromatous. The heart weighed twenty ounces. The left ventricle, forming the greater part, was much hypertrophied and rather dilated towards the apex. At the apex, on the septal side, was an irregular laceration of the muscular substance running through into the right ventricle, and also outwards into the sub-pericardial fat; both this and the edges of the laceration were infiltrated with blood. The pericardial sac contained about a pint of clotted blood. The valves on both sides were healthy, though the aortic and mitral valves were slightly thickened with atheromatous deposit. The first inch of the aorta was also moderately atheromatous, and the coronary arteries were excessively calcareous, both of them being narrowed in their main trunk. The branch running down the anterior aspect, corresponding to the septum and to the laceration, had its coats changed at more than one spot by altered blood-colouring matter of old date. The muscular tissue, notwithstanding the disease of the vessels and the laceration, appeared to be very good; its colour was of a natural deep-red, and it displayed no unnatural softness or fatty change. The cause of death being ascertained, no further investigation was considered necessary as regards other organs.

MEDICAL MISSION WORK IN KASHMIR.—At the hospital at Srinagar 5402 new patients were registered during 1883 and a total of 12978 visits paid. The number of in-patients was 391, the average stay of each of these being twelve days. In the Leper Asylum thirty-two patients were treated, seven being operated upon. The financial condition of the institution is satisfactory, and the year closed with a considerable balance in hand. Dr. Neve, in his report, states that such diseases as phthisis, pneumonia, pleurisy, rickets, scrofula, and aneurysm, are in Kashmir very rare, almost unknown, notwithstanding cold, poverty, insufficient food and clothing, overcrowding, and syphilis.

Malhauntem estalia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

GUY'S HOSPITAL.

CASES OF FRACTURE OF THE BASE OF THE SKULL.

(Under the care of Mr. BRYANT.)

THE following series of cases of fracture of the base of the skull illustrates some of the more important complications attending this lesion:—

CASE 1. *Fracture of Base of Skull; Hæmorrhage from Left Ear; Right Facial Paralysis; Recovery.* (From notes by Mr. Hilbers.)—John C——, aged sixty-three, a warrant officer, was admitted on Nov. 2nd, 1882. He had been knocked down by a horse and cart, and was brought to the hospital insensible. Soon after admission he became sensible, but seemed dazed and was very sick. There was no superficial wound of the scalp, but there was copious hæmorrhage from the left ear. On the following day he was sensible, but complained of pain in the head and stiffness about the right arm. He was still giddy, and had been sick several times. There was paralysis of the right side of the face. The pupils were equal and acted well to light. Temperature 98·2°; pulse 80. Ordered an ice-bag to the head, and to have five grains of calomel at night. On the 7th he complained of throbbing pain in the head and pain at the back of the eye. On the 11th he slept and ate well, and the paralysis had almost entirely disappeared. On Dec. 5th he was discharged well, but was advised to keep quiet for five or six weeks.

CASE 2. *Fracture of the Anterior Fossa; Subconjunctival and Nasal Hæmorrhage; Separation of Lower Epiphysis of Radius; Death; Necropsy.* (From notes by Mr. F. Knagga.)—James H——, aged twelve, was admitted on February 24th, 1883. He was sliding down the balustrade of a warehouse, when he fell from the third floor. On admission, at 2 P.M., he was quite insensible; pupils dilated and unequal, the left being the larger; no bleeding from the ears, but some from the nose and mouth (he fell upon his face); respiration irregular, but not of the Cheyne-Stokes character. The left eyelid was much swollen, and the lower lid was of a bluish-black tint. There was a slight puffy swelling of the anterior half of the left temporal fossa. There was, in addition, the typical displacement of a Colles' fracture of the lower end of the radius; crepitus not felt. The right knee was slightly flexed and passed over the front of the left leg. There was very little enlargement of the knee-joint, but fluid could be felt on both sides of the patella. At 4 P.M. the right pupil contracted and dilated in a rhythmical manner without reference to light. At 5 P.M. both pupils contracted and dilated alternately; both eyes turned to the right, and then a twitching of the whole eyeball occurred, and the whole eye was markedly directed outwards, but occasionally there was a return movement of the eyes to their proper position. On the left side the subconjunctival hæmorrhage was very distinct. The eyelids were difficult to open on account of swelling. Respiration 28; snoring as in normal sleep. Well-marked anchylosis of right knee. At 11 P.M. the skin was bathed in perspiration; loud rhonchi could be heard all over the chest; no spasms or twitching.—Feb. 25th: Restless; respiration stertorous and regular. At 1 P.M. the respiration was rapid and irregular; limbs perfectly flaccid.—26th: The patient died at 12.5 P.M. The temperature rose more or less regularly from 96·6° on Feb. 24th to 105·4° on the 26th, the time of his death.

Necropsy.—There was a contusion about the left orbit, and a fracture of the left orbital plate of the frontal bone. No injury to the brain was observed. There was a fracture of the styloid process of the vena, and separation of the lower epiphysis of the radius backwards. The organs were healthy, with the exception of a slight hæmorrhagic effusion below the capsule and under the surface of the liver. There was no hæmorrhage into the left orbit. The fracture extended obliquely backwards and inwards on the orbital plate of the frontal bone to the cavernous sinus, rupturing the ethmoidal vessels, as the ethmoidal bone was seen to be implicated in the sinus. No inflammation in the membranes existed.

CASE 3. *Fractured Base; Crushed Mastoid Process; Escape of Cerebro-spinal Fluid for eight days from Ear; Fractured Lower Jaw; Recovery.* (From notes by Mr. Ironson.)—Walter Edward C——, aged six, was knocked down by a light van, the wheel of which went over his head. On admission, on April 20th, 1883, the child was found to have a large wound on the left side of the head, and the head and face were much bruised and abraded. There was a sero-sanguineous discharge from the ear. No paralysis existed, and the patient was quite conscious. There was a great depression on the left mastoid process, where the bone had been crushed, and also a considerable contusion about the left angle of the jaw. The right side of the neck and face was much swollen, and the right eyelids were completely closed up. On the 24th the discharge from the ear still continued, but the swelling of the face had subsided. The right eyelid was open and the pupils dilated, acting, however, equally, though sluggishly. On the 27th the child was much brighter, and the wound was healing up. A small pocket of pus was opened by incision at the apex of the mastoid process. On the 28th the flow of cerebro-spinal fluid ceased. On May 3rd the patient's face was much swollen on the left side, about the lower jaw. The dresser thought he heard crepitus near the symphysis. On the 8th there was considerable fluctuation observed near the fracture. Next day the swelling over the lower jaw was incised, and some white pus escaped. On the 21st there was some purulent discharge from the left ear, but the wounds were doing well. On June 16th the patient was discharged.

CASE 4. *Fractured Base of Skull; Scalp Wound; Facial Paralysis on Left, and subsequently on Right, Side; Mastoid Abscess; Incision; Prolonged Incoherence; Recovery.* (From notes by Mr. Humphreys.)—Mary Ann K——, aged twenty-four, was admitted on Dec. 5th, 1882. She was a drunken and bad character. On the evening of the 3rd she fell into a cellar, and was picked up and left to lie upon the floor all night. Next morning she was found to have bled a good deal, and to have been sick. On the evening of the 5th, as she had not recovered consciousness, she was taken to the hospital. On admission she was found to be collapsed and pulseless. Brandy was injected, which revived her, but did not restore consciousness. She had a scalp-wound to the left of the occipital protuberance of a punched-out appearance. There was slight left facial paralysis. She had a bruise on the chin and several bruises on her body. Her right pupil was larger than the left. She had perfect movement of her extremities. She was sick on admission, but not afterwards. Ordered iced milk, and five grains of calomel at once. On the following morning she was still unconscious, and fluid was escaping from the ear. Her face turned to the right, and resumed that position if moved. On Dec. 7th the paralysis of the face was more marked, but next day she became half conscious. On the 11th a great deal of pus and fluid escaped from the left ear. On the 12th she became very noisy. Two days later a slight fluctuating swelling appeared anterior to the ear. Above and below the mastoid process were two other swellings, and a third behind the ear, and discharging through it. On the 20th the patient was able to talk well. Two days later a great deal of bad smelling discharge escaped from the left ear. On the 27th there was less discharge from the ear, and the swelling in front of it had subsided. On Jan. 2nd the skin had become red over and around the ear; and on the 5th some necrosed bone could be felt in the abscess behind the ear. There was a slight rash on the face and forehead. On the 9th there was still some paralysis of the right side of the face. It was stated that the woman had been rather "silly" for the last few days, continually giggling and making disconnected remarks when spoken to. On the 13th, however, she seemed more collected. There seemed to be complete paralysis of the right side. On the 16th the patient had more control of the right half of the face. Some blood-stained discharge came from the abscess behind the ear. On the 22nd the patient was rather cyanotic. She complained of hunger and seemed more sensible. On Feb. 17th the woman went out, still half foolish, the wound behind the ear continuing to discharge. The occipital wound was healed, and in general health she was improved.

SOOREE CHARITABLE DISPENSARY.

FRACTURE OF SKULL; EXTENSIVE EXTRAVASATION OF BLOOD ON DURA MATER, PRODUCING COMPRESSION OF BRAIN; TREPHINING; PARTIAL RELIEF OF SYMPTOMS; DEATH.

(Under the care of Dr. G. C. ROY.)

DURING a drunken affray in a liquor shop, the patient was knocked down by a blow on the head from a heavy stick. He fell down insensible, but recovered consciousness after a while and was able to speak, but soon relapsed into a state of insensibility, in which condition he was taken to the dispensary next morning, and placed in bed.

When seen, the man was unconscious and very restless, tossing about in the bed, and he made no response to questions put to him. His pupils were normal; the breathing was at times natural, with a tendency to stridor. Pulse 72, small. There was no paralysis, but the limbs were rather rigidly flexed. The scalp at the junction of the sagitto-coronal suture was contused and puffy, and a depression was felt in the skull just outside this line and to the left. A crucial incision was made over the part, and the trephine applied over the depressed segment. A linear line of fracture traversed this space, but the depression was limited to the outer table, and was caused by the condensation of the bone from the force of the blow. A probe was gently passed between the bone and dura mater to scoop out any blood that might have been effused on its surface, but only a few small pieces of clot could be thus removed. The wound was dressed with cotton soaked in weak carbolic acid.

Next day there was a return of consciousness. The patient opened his eyes when spoken to loudly. He also put out his tongue, and pointed to his head as the seat of pain. He was, however, very dull and stupid, and could not speak. The progress was impeded next day by an attack of erysipelas, which travelled from head to face and neck, and after three days left him in a very exhausted condition.

For the next three days the patient's condition was hopeful. The wound was granulating, and he could answer questions by signs, though still unable to speak. He took a fair quantity of rice and milk. The rigidity of the limbs disappeared, but the pulse went up to 116, and a tendency to pneumonia of the left lung was manifested. On the ninth day after operation he was decidedly worse, the consolidation of the lung had progressed, and he died quietly at night.

Necropsy.—The extensive fracture passed across the squamous portion of the left temporal bone, and bifurcated at the external angle of the orbit, enclosing a bit of loose spiculum. Another line of fracture radiated upwards from the centre of the first, and terminated at the seat of operation. A thick layer of coagulated blood rested on the dura mater just opposite the temple—dimension 5 × 3 × 1 inch. At the lower part it was an inch thick and adherent, but gradually thinned on the top. Another patch of coagulated blood was found on the right side, opposite the parietal eminence. The dura mater and brain were healthy. The left lung was in the first stage of hepatisation. Other organs were healthy. The wound was healthy-looking.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Medical Section held on May 16th,

Mr. JOHN B. STORY exhibited a patient suffering from Atrophy of both Optic Nerves, and Paralysis of the Olfactory Nerves and of the Sensory Division of the Right Fifth Nerve. The patient was an unmarried woman, aged thirty-two, who had enjoyed good health till the winter of 1882-83, when she began to suffer from a violent pain in her head. The pain later on became so violent as to confine her to bed, where she remained for some months in the spring and summer of last year. After a time she became completely unconscious, and when her consciousness returned (about July, 1883) she found her senses of sight and smell totally lost, and sensation absent from the right side of her face and the little finger and ulnar side of the ring finger of her right hand. She noticed at the same time a defect in the sense of taste in the anterior portion of the tongue at the right side. The examination of the patient completely established the truth of her statements, with the exception of the paralysis of the fingers, which did not then appear to exist. Corneal and conjunctival sensibility was completely absent, and the palpebral and lacrymal reflexes connected with it, while the cornea itself was perfectly healthy, and the tension of the right globe rather above that of the other eye. He considered the case to be one of cerebral tumour, but could not assign any definite locality to the supposed new growth. The atrophy of the nerves was undoubtedly produced by optic neuritis. He commented on the various theories explanatory of the connexion between papillitis and brain disease, and upon the current views as to the production of neuro-paralytic keratitis. The secretion of saliva from the right parotid gland was, so far as careful testing with vinegar could ascertain, completely abolished, that from the left gland being perfectly normal.—The CHAIRMAN (Dr. H. Kennedy) would connect the symptoms with a tumour at the base of the brain, implicating particular nerves or parts. There seemed to be less vomiting than usual in the case related.—Dr. C. J. NIXON considered that if Mr. Story was perfectly satisfied there was a lesion of both nerves of smell, and at the same time a lesion affecting some of the fingers of the hand and the forearm, it would be perfectly possible to account for all the phenomena that existed on the idea of an isolated tumour. It was remarkable to find that, with the implication of the sensory division of the fifth nerve, there was complete loss of the sense of taste on the corresponding anterior portion of the tongue. This was directly in opposition to a case recorded by Althaus, in which he excluded the fifth nerve as administering to the sense of taste on the antero-lateral region of the tongue.—Mr. STORY, in reply, said he had tried iodide of potassium for some weeks without alteration in the symptoms. In answer to Dr. Nixon, he pointed out that they were all familiar with the fact that loss of sense of smell followed paralysis of the sensory portion of the fifth nerve. In this case a probe might be put up the right nostril without the slightest effect; but if the left were touched in the same way, the patient shrank with pain. Assafœtida, valerian, oil of cloves, or ammonia, had no effect on the right side, whereas on the left the sensation was produced consequent on inhaling strong smelling salts.

Dr. C. J. NIXON read a paper on Reflex Paralysis, in which he summarised the different views which had been held in favour of and against the theory of this form of paralysis. He first examined the class of cases of paralysis which are usually cited as caused by reflex influence—viz, amaurosis from affections of the fifth nerve, and paralysis of the orbital nerves from a like cause. Having shown that these cases may be explained without reflex mechanism, he next examined the evidence as to the existence or non-existence of reflex paraplegia. Examining the views of Brown-Séquard, Gull, Leyden, and others, and the experimental observations on the subject, he directed attention to the absence of any true conception of the mode in which paralysis by reflex action is brought about, except we understand it to be produced by inhibitory influence; so that reflex paralysis, if it have any meaning, must be inhibitory paralysis. This name had at least the advantage of suggesting the way in which the phenomena of disease are produced. Dr. Nixon thought, however, that there was no necessity to admit the existence of an inhibitory paralysis, as, taking for instance the cases recorded as reflex paraplegia, they could arise in different ways—as an ascending neuritis, which sets up myelitis from extension of inflammation along the veins to the spinal cord, or from a lumbar-sacral neuritis, which descends along the sciatic nerves.—Dr. MCSWINEY called attention to the so-named reflex paralysis following wounds, of which Weir Mitchell had given many examples, including paralysis affecting the upper extremities, right or left, where a wound had been received in the lower extremities, right or left.—Dr. BENNETT considered Dr. Nixon's paper open to the objection characterised by lawyers as "pleading double." In his hospital experience Dr. Nixon had never seen a case of reflex paralysis, while he quoted instances of inhibitory nerve influence, which he held to be another name for reflex paraplegia. It was difficult, therefore, to follow his argument.—Dr. WALTER G. SMITH, looking at Dr. Nixon's conclusions as a whole, said his views must to a great extent be felt to be in accord with those of modern teaching, supported by the pathology of nervous diseases; so that very few, if any, physicians or surgeons would now accept Brown-Séquard's teaching in his interesting lectures on Paralysis of the Lower Extremities. Caution

Digitized by Google

must be observed in dogmatising too strictly as to what could or could not happen in the domain of the nervous system. Dr. Nixon did not sufficiently allow for the extremely important effects of local sensory irritations, which include both the skin and internal skin or mucous membrane—in other words, stimulation of a limited area of the sensory nerves. The curious thing was that, no matter what part of the skin was stimulated, similar effects followed. It was known that death occurred during the early stage of inhalation of anæsthetics. Again, tickle the inside of the thighs and in a bright light the pupils would be seen to dilate. It was difficult to say what channel that influence travelled up, yet it was the influence of reflex action. Indeed, it was well known that the vomiting centre could be approached by many channels. Modern teaching had undoubtedly narrowed the field of reflex diseases, and while they should be thankful to those inquirers who had cleared away so much obscurity, it was too soon to urge anything positive as to the phenomena being a reflex arrest of function, without speculating that the mechanism by which it was produced might not arise in the body.—The CHAIRMAN called Dr. Nixon's attention to a clinical aspect of this question. He had himself put on record a host of cases of children, from five to seven months old, who had suddenly lost power of one arm, and in these the scarification of a gum or an active purge produced a cure at once. Thus the reflex paralysis was in these cases due to irritation of the mouth or the accumulations in the intestines.—Dr. NIXON replied that he had used the term "inhibition" first, as a step in getting rid of the theory of Brown-Séquard that the paralysis was due to reflex spasm of the bloodvessels of the spinal cord; if not to that, it was due to something else, a number of things, and he took inhibition as one to which it might be due; and he had said there was no necessity for introducing this explanation of the theory of disease at all, inasmuch as it had been established that the paraplegia assumed to be reflex was due to causes which had been ascertained, as an ascending neuritis or a descending neuritis, or a neuritis established by the travelling up of inflammation along the veins. The received explanation of the results of the operations he had cited was that they were due to what was understood as the phenomenon of inhibition. If they were not satisfied that the cases of paraplegia recorded had most distinct and positive pathological lesions to explain them, then the theory of paralysis by inhibition was the one that would satisfy the scientific requirement best. But in the absence of necessity there was no use introducing a new term into medical pathology. With regard to Dr. Walter Smith's observations as to the effect of stimulation, Brown-Séquard had mentioned that peripheral stimulus might act in three different ways—it might influence secretion, or the condition of the bloodvessels or of the muscles. In his paper before the section, he had confined his observations to the condition of the muscles that might be said to be influenced by peripheral irritation. He did not discuss the condition of the bloodvessels such as would be brought about from irritation of an extensive surface of the skin following a blister, &c. Dr. Smith seemed to have dealt with spasms as being connected with paralysis. There was not the slightest doubt that peripheral irritations of various kinds—worms in the intestines and teething—produced convulsive phenomena; but it was quite a different thing with irritation transmitted to the cord. Irritation was supposed to pass to the motor area, and yet the usual result was not attained. Although he had seen a great many cases of paralysis, he had never seen one that he could connect with any of those cases of local irritation such as teething, or that got well on suddenly lancing the gum, and he did not see why paralysis should be cured by such a simple procedure. The object of his paper was to show that such a thing was a physiological impossibility.

On the motion of Dr. Grimshaw, the remaining papers on the agenda were, for want of time to be read, referred to the Publication Committee.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on July 4th, Professor Humphry, M.D., F.R.S., in the chair,

Mr. BALDING (Royston) exhibited a specimen of Sarcoma of the Left Tonsil, taken from a female aged fifty-three, who first came under observation on Aug. 7th, 1883, in consequence of sudden and profuse hæmorrhage from the mouth, which appeared to be arterial. At this time there was sore-throat of a month's duration, with some ill-defined indurated swelling in the left submaxillary region, great fetor of breath, and complete fixity of the lower jaw, which rendered any examination of the mouth or throat impossible. This alarming hæmorrhage soon subsided, and only recurred once, to a less amount, ten days later. On Nov. 8th the swelling in the neck had slowly increased, without having become either very painful or tender, and some deep-seated fluctuation now appeared to indicate the existence of pus. This was easily reached and evacuated, and it was estimated that an ounce was let out on the first day. This gave some slight relief, and at the end of a week the abscess had completely healed. Ten days later a second abscess was detected and opened, and this healed rather quicker than the first. These abscesses were just on a level with the upper margin of the thyroid cartilage, the second posterior to the first. There was no subsequent suppuration. During the time of formation of these abscesses there was considerable swelling of the tongue, especially in the left half, so that for a few days it could be scarcely kept within the mouth, but after the second abscess was opened the swelling subsided, and was almost immediately followed by further swelling of the tongue, this time principally affecting the right side, so that it was protruded from the mouth and firmly grasped by the teeth. The swelling subsequently subsided so as to allow the tongue to be returned within the mouth. The patient died on Jan. 12th; the swelling in the neck had for a fortnight previous to death encroached on the trachea and caused some difficulty in breathing. During the whole course of the case the patient was able to take fluid nutriment with but little difficulty. The necropsy showed a firm growth involving the left tonsil; it extended into the submaxillary region, infiltrating the glands and surrounding structures. The epiglottis was also partially destroyed. Microscopically, the growth proved to be a round-celled sarcoma.

Mr. MANBY (East Rudham) related a case of Morphia Poisoning unsuccessfully treated by Hypodermic Injection of Atropia. At 11.30 one evening he was hastily summoned to a lady who was known to be suffering from internal cancer, with considerable intra-peritoneal effusion &c. He found her lying on her back, with livid face, dropped lower jaw, closed eyes, and apparently dead. Shortly after, respiration commenced, in Cheyne Stokes' manner, with palatal stertor. The skin was moist; pulse 108, soft, and rising with the breathing to 120 or more; pupils contracted to pins' points, and insensible to light; conjunctivæ insensate to the touch. The most violent irritants applied to the trunk had no effect in exciting reflex action. On inquiry, he was informed that the patient had that evening returned from London. The previous evening she had an ineffective hypodermic injection of morphia, in consequence of which the nurse, obeying instructions given her to increase the dose if necessary, without any clearly defined limit, had about 10 P.M. injected a larger quantity, corresponding to at least a grain and a half. It was clear also, from the account given, that the needle had not been inserted on the previous occasion. The symptoms supervened very soon after the injection. Mr. Manby made use of all the ordinary means to arouse her, but without success. He then, at 11.45 P.M., injected beneath the skin of the arm five minims of the liquor atropiæ, without effect on the pupils or respiration. At 12 P.M. he injected another ten minims, which had a slight stimulating effect on the pulse, so at 12.15 he added ten minims more. Then, after using a powerful magneto-electric current to the præcordium, another injection of five minims was repeated. No improvement followed, and the patient died about 1.30 A.M., three and a half hours after the morphia injection. The amount of liquor atropiæ injected was thirty minims, or a quarter of a grain of atropine.

Dr. RANSOM related five cases of Croup. He said the term "croup" was used to indicate a group of symptoms. All the cases were children under six years of age. Three died and two recovered. The trachea was opened in one of the fatal cases. The symptoms in all the cases were very much alike. There was at first little or no constitutional disturbance, and in two cases at the beginning no rise of temperature. The fever in no case exceeded 101° F. the tonsils were swollen, and there were patches of exudation on them and on the aorta, but very little appearance of inflammation. All the fatal cases died from asphyxia; in one,

Digitized by Google

after tracheotomy had been performed, the disease spread below the tube. The two recoveries were brothers. The treatment was various. The two latter took from one to two minims of a strong solution of perchloride of iron every hour. In no case was any contagiousness exhibited. If these cases were diphtheria, how were the exceedingly mild constitutional symptoms to be explained? Perhaps by supposing that although the disease were in truth diphtheria, yet the amount of poisoning was small or the number and reproductive activity of the micrococcus limited; hence also its non-contagiousness; but the local disease was, in young children, for anatomical reasons, sufficient to cause asphyxia.

Reviews and Notices of Books.

Die Tuberculose der Knochen und Gelenke. Bearbeitet von FR. KŒNIG. Mit 18 Holzschnitten. Berlin: August Hirschwald. 1884.—This excellent account of the tubercular diseases of the bones and joints is founded on the results of personal observation of the author; it is dedicated to the distinguished Volkmann. We may perhaps best indicate the scope and character of this work by describing some of the contents of the chapter on the treatment of tuberculous affections of the parts under consideration. The author says in the beginning of the section in question, that since the white swelling of joints is regarded as an example of tuberculosis, it is obvious that the treatment of this localisation of the disease must be conducted on the same general principles as guide us in considering the treatment of any other tuberculous disease. Amongst other objects, one of our chief aims must be to destroy the infective agents, the bacilli and their spores, by means of specific remedies. Up to the present these specific agencies have not been discovered. Whilst admitting that the preparations of arsenic, iodine, and mercury, with cod-liver oil, saline baths, and the sea coast, are beneficial in many cases of tuberculosis of any part of the body, Dr. Kœnig does not place much reliance on them, for he thinks many cases go on just as well without their employment. He has not had any experience of Davos and the mountain cures in surgical cases. Contrary to his earlier teaching, Kœnig does not now look with favour on the injection into the diseased tissues of solutions of carbolic acid and similar agents. The author is an advocate of the operative interference in almost all cases of tubercular bone and joint disease. In cases where the diagnosis of a local affection of any part of the articulation is probable, the removal of the diseased centre is recommended by simple gouging or scraping away, under proper precautions of strict cleanliness. Where the extent of the disease necessitates it, resection of a greater or less amount of the diseased structures is regarded as the proper line of treatment. The bloodless method of operation is highly spoken of, and the employment of iodoform dressings is strongly recommended. Free incisions are praised in suitable cases. The results of timely resection in the author's hands have been very satisfactory. Separate chapters are devoted to the consideration of tubercular disease in each of the principal points of the body—viz., hip, knee, ankle, tarsus, shoulder, and elbow. With regard to the results of excision of the hip-joint, the author says but little here, promising to say more at the Surgical Congress, but he is evidently inclined to look favourably on the operation.

Specificity and Evolution in Disease. By W. J. COLLINS, M.D., B.S., &c. London: H. K. Lewis. 1884.—This paper, which was read before the Abernethian Society of St. Bartholomew's Hospital, is well worthy of perusal. It is an attempt—and not altogether an unsuccessful one—to apply the evolution theory to the explanation of the relations between specific diseases, and to advance facts in support of the doctrine that there is no sufficient ground for the hard-and-fast lines of demarcation between these diseases and simple inflammatory affections that are generally adhered to. We cannot but think that Dr. Collins in some places pushes his views too far; as, for example, where he implies that tubercle has been robbed of its specific nature by the pneumonic doctrines of Niemeyer, or that gonorrhœa can arise *de novo*. Indeed, from the standpoint he assumes, it would almost appear as if to be an evolutionist one must also be a heterogenist; but we hold that this does not necessarily follow. The hypothesis that most of the varied forms of disease now known to us have sprung from some ancestral type, and that modifications in their nature have largely depended upon the conditions around them, is not improbable, and harmonises with the biological doctrines which are making so much progress in respect to the causes of disease. It is a different matter, however, to admit that the specific distinctions which have led clinical observers to separate diseases from one another, and which pathological inquiry confirms, have no essential basis at the present time. To do him justice, however, Dr. Collins admits there is a relative specificity, but not an absolute one; and if only he would follow biologists in observing more caution in receiving evidence upon the *de novo* origin of morbid germs, we see nothing in his able argument from which we need seriously differ. He has done good service in directing attention to the subject, which is capable of very wide application.

Sleep-walking and Hypnotism. By D. HACK TUKE, M.D. London: J. & A. Churchill. 1884.—This brief essay is given in memoriam of William Samuel Tuke, the author's lamented son. Six years ago Dr. Tuke and his son prepared and printed a series of questions on the subject of sleep-walking, which were then widely circulated; but from two or three causes nothing much came of the attempt to enlarge our knowledge in that direction. Dr. Tuke now again takes up the subject, and has written a readable, entertaining, and instructive account of sleep-walking. The circular of inquiry has been reproduced at the end of this account. A case of spontaneous and one of induced sleep-walking are next described. The section following is concerned with the mental condition in hypnotism or artificial somambulism. To form an idea of the cerebro-mental condition of the hypnotised is not a difficult matter for the speculative mind, but whether such an idea would stand the test of ordinary objections is more than doubtful. Taking Hughlings Jackson's standpoint of mental phenomena regarded as matters of increasing complexity and diminishing stability or organisation, it is not difficult to conceive of the suspension or continuance of various acts of the mind under the influence of several forces, inhibitory or otherwise. But whether such views are merely different modes of stating the same problem, or truly, though but partially, explanatory in their character, is more than we can say. It would land us into a hopelessly long discussion if we attempted to unravel the knots of the skein which we have produced by saying what little we have. We can, however, confidently recommend Dr. Tuke's little work to the attention of all interested in psychological matters.

Western African Hygiene; or, Hints on the Preservation of Health and the Treatment of Tropical Diseases, more especially on the West Coast of Africa. By CHARLES SCOVELL GRANT, M.D. Pp. 51. London: Stanford. 1884.—This is the second edition of a work intended for the use of non-professional persons who are called upon to reside on the West Coast of Africa. Its object is not to supersede skilled medical advice and assistance when these can be obtained, but to give such instructions as may prove useful in preventing disease, and in treating it when such assistance cannot be procured, or until it is available. The book

Digitized by Google

has the great merit of being written in plain intelligible language, and the instructions for the prevention of disease and for its treatment, both during the active stage and the period of convalescence, appear to be judicious.

A Medical Guide to the Principal Health Resorts of Northern England. With new chapters on Whitby, Scarborough, Redcar, Saltburn, Harrogate, &c. By RICHARD ELLIS. Pp. 175. London: Scott. 1884.—This is a new edition of a guide-book published last year. It gives an account of the more important health resorts in the North of England, classified into seaside, inland, and mountainous or upland health resorts. It cannot fail to prove useful in helping persons to select a place where they may spend their holiday pleasantly in England, with the advantages of sea-bathing or of mountain air, as may be most desirable. It contains a good deal of historical information regarding the various places described, the objects of interest in their neighbourhood, and the season of the year best suited for their enjoyment; but it is more of a popular than a professional guide, and would advantageously bear pruning in some of its flowery descriptions.

Health Studies. By H. SINCLAIR PATERSON, M.D. Pp. 209. London: Hodder and Stoughton. 1884.—Although no information is given on the subject, we are disposed to think that this volume consists of lectures addressed to some society composed of young men, upon various subjects connected with health. It is well written, contains much information and sensible advice, and the tone throughout is good. It is a work which should prove useful to the class for whom it was apparently written.

La Santé du Peuple. Par L. EVRARD. Pp. 229. Bruxelles: A. B. Lebegue.—This is a work to which the Royal Academy of Science &c. of Belgium awarded a prize of two thousand francs. It treats of the general rules for preserving health; nursing the sick, and the aid to be given in cases of sudden illness, and of accidents and injuries; the measures to be adopted in epidemics; the subject of small-pox and vaccination; and the organisation of a public health service. It appears well calculated to spread sound information among the educated classes of Belgium on the subjects of public health and the first assistance in sudden illness and accidents.

The Laws of Health: Physiology, Hygiene, Stimulants, Narcotics. For Educational Institutions and General Readers. Copiously illustrated. By JOSEPH C. HUTCHISON, M.D. Pp. 223. New York: Clark and Maynard. 1884.—The object of this work is to supply a useful and intelligible text-book for grammar schools, and those of a higher grade, on the subjects of physiology and hygiene. We regret that we are unable to congratulate the author on having effected the important object he had in view. The book does not appear to us to be one which would be generally understood by the class of boys who attend grammar schools, and some of the illustrations would be very likely to mislead.

The New York Medico-Legal Journal. June, 1884.—This volume contains several papers of great interest. That by Dr. H. Maudsley on the Moral Sense and Will in Criminals is written in the author's best style. Dr. C. H. Hughes gives a contribution on "Moral" Insanity. The article of greatest value, looked at from a practical standpoint, is by Dr. G. Johnson on Poisoning by Canned Foods. The writer relates cases of poisoning from the ingestion of tinned tomatoes, and conclusively proves that the deleterious agent is a mineral poison, either verdigris derived from copper kettles used in preserving fruit and vegetables, or chloride of zinc employed to solder on the caps of the tins. Dr. J. M. Carnochan has a brochure on Cerebral Localisation in relation to Insanity. Notes of Transactions of Societies, reviews of current literature, and other miscellaneous matter, complete an unusually good number of this excellent journal.

"REARING OF HAND-FED INFANTS."

To the Editor of THE LANCET.

SIR,—I read with much interest the abstract of Mr. Owen's lecture on the above subject at the Health Exhibition in last week's LANCET, but I was disappointed at his laudation of diluted cow's milk with a little sugar and a pinch of salt as a satisfactory substitute for the natural maternal aliment. My own experience at least does not confirm his, and I have known many infants who would have succumbed to deranged stomach and bowels, and virtually have died of starvation, had they been kept to the diet recommended by him.

Since the publication in THE LANCET of March 16th, 1878 (p. 390), of Dr. Frankland's method of preparing artificial human milk, I have always resorted to this for all delicate infants deprived from any cause of natural nourishment. Dr. Frankland states that he "saved the life and thoroughly nourished one of his own children for the year during which he consumed it." He states that "human milk is sweeter, but contains less casein and salts than cow's milk; the butter is about equal in quantity." The casein is in excess by about one-third in cow's milk; this it is which causes the digestive troubles of the little one, great cakes of hard curd being often rejected by the stomach, or, if passed on to the bowels, setting up irritation, diarrhœa, or enteritis. If you simply dilute the milk with an equal volume of water, you may reduce the casein to a quantity sufficient, but you rob it of half its proper amount of butter and saline matter, both of which are most important for the infant's growth and nourishment. What is requisite to be done? Simply to remove one-third of the casein, and add the required amount of sugar; no "pinch of salt" will be required if the milk is not diluted, as the cow's milk contains sufficient saline matter. The preparation of this artificial milk is accomplished in about ten minutes, and it will be gladly undertaken by even "the lazy nurse," for the sake of the better health and rest acquired by the baby thus nourished. To prepare it, allow half a pint of new milk to stand for about twelve hours; remove the cream and add it to one pint of new milk, as fresh as possible. Into the half pint of skim-milk put a piece of rennet about an inch square, to be obtained of the butcher. Set the vessel in warm water till the milk is fully curdled, which requires from five to fifteen minutes, the rennet being removed as soon as curdling commences, and put into an egg-cup for future use, as it can be employed daily for a month or two. Break up the curd thoroughly and separate the whole of the whey, which should be rapidly heated to boiling, when a little more casein separates and may be removed by straining; 165 grains (about two teaspoonfuls) of powdered sugar to be dissolved in this hot whey and the sweetened fluid added to the pint of new milk (and cream). It is then ready for use. With Dr. Frankland I can affirm that I have saved the lives of sundry children that would assuredly have died without this artificial milk. The little extra trouble is thought nothing of by mother or nurse who has once tried it. The above quantity is generally sufficient for a new-born infant for the twenty-four hours, and, except in the hottest weather, will keep sweet for a similar period. My apology for thus troubling you must be my desire that it should be better known and tried by practitioners before recommending the endless variety of biscuits and infants' food, as it is, indeed, almost a *fac simile* of the natural nourishment.

I am, Sir, yours truly,

Spondon, Derby, Aug. 18th, 1884. B. WALKER.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a meeting of this Association held on the 14th inst., Dr. Hime, who presided, made a few observations on woolsorters' disease—a subject which has lately been productive of a good deal of interest and anxiety amongst medical men and others. Dr. J. M. Fox afterwards made some remarks on a recent outbreak of fever at Bowdon, and, referring to the conviction for libel of the newspaper editor who published the medical officer's report, urged the necessity of an amendment of the law of libel as applying to such "discharges of an inconvenient public duty." A brief discussion followed.

THE LANCET.

LONDON: SATURDAY, AUGUST 23, 1884.

WHILE cheerfully recognising the extreme interest of Dr. KOCH'S investigations into the nature and cause of cholera, of which we have been gratified to give our readers an early and full account, it is quite obvious that they do not at present supply the material for much guidance in the treatment of this much-dreaded disease. It is fair at least to hope that we shall not have many cholera cases to treat. To be forewarned is to be forearmed, and certainly our sanitary authorities have had warning enough. The disease is not one which overpowers us all at once. It has to be introduced from an infected place more or less directly, and to spread slowly from one individual to another and from one house or place to another. We may fairly trust to our medical officers of health giving a good account of any suspicious case, and we may rely on medical practitioners everywhere cheerfully co-operating with them in their efforts for isolating cases and restricting the spread of a disease which appears, despite Dr. KOCH'S somewhat discouraging conclusions as to the value of disinfectants, to be so much more preventable than curable. When the College of Physicians ventures to assure the public that, "with reasonable precautions," those who wait on the sick are not more liable to the disease than others, it certainly elevates the question of such precautions into the first rank of importance.

We the less dwell on this part of the subject, as it may be assumed that every sanitary authority, by public instruction, will place before its constituents the best ascertained facts as to the means of disinfection. Where excreta and infected garments cannot be destroyed by fire, which is certainly the most satisfactory way of dealing with them, we should recommend that the excreta be received into a vessel containing fluid consisting of one part of carbolic acid to nineteen of water, or of a solution of sulphate of iron (green vitriol) of the strength of one ounce to a pint of water. The excreta must be kept in these solutions three or four hours. Stained and infected linen should be soaked in such a solution of carbolic acid and hot water for twenty-four hours and then boiled.

Our object just now, however, is not so much with questions of disinfection as with strictly medical questions of treatment. There is one point on which Dr. KOCH is in practical agreement with medical practitioners—that is, the wisdom of rectifying all ordinary gastric and intestinal disorders during the prevalence of cholera. Nothing is more striking in his conclusions than the bactericidal function of the human stomach when in health and when reasonably treated by its owner. He never found the comma bacillus in the vomited matters, except where he had reason to suspect that they contained accidentally some fæcal contaminations. The stomach which is affected with gastric catarrh, whether from drinking or over-eating, chill, or other cause, is likely to supply an amount of mucus-protection to the cholera bacillus which will secure its transmission unkilled into the intestine, especially the ilgum, there to do its deadly work. It is an old point of medical observation that drunkards and other disorderly livers fall an easy prey in times of cholera. They will do well to mend their ways in time—to live "soberly and righteously,"—and, if any indigestion or dyspepsia survive such a change in their habits, to apply without delay to their medical advisers. It is a vulgar impression in cholera times that nips of brandy have a preventive effect. Nothing can be more incorrect. Such a practice would be well calculated to produce that gastric catarrh which, as KOCH and all practitioners of experience agree, is most apt to give the cholera poison its best chance of operating on the intestine.

There is nothing in KOCH'S researches contradicting the general opinion of the profession that by far the best thing in cholera epidemics is to take measures to bring cases of diarrhœa under early treatment, and to employ such remedies as are of a corrective and astringent character. The College of Physicians has done good service in recommending that in any place visited with cholera house-to-house visitation should be instituted. In this way, not only are cases of diarrhœa prevented from drifting, but opportunity is gained for seeing the homes in which they occur. The nature of the remedies to be used for diarrhœa will vary somewhat according to the nature of the case and the judgment of the practitioner. In some cases of gastro-intestinal catarrh, with little evacuation, such medicaments as bismuth and soda will be enough to correct the disorder, but where copious fluid evacuations from the intestine have begun they should be regarded as in themselves serious, and first objects of treatment. No doubt there are cases of cholera, especially in the East, fatal without these, or in which the evacuations are disproportionate to the shock and collapse. But this is not the rule in this country, and indeed is exceptional. In the great majority of cases where the evacuations can be early controlled the constitution of the blood is preserved and the disease may be cured. Where there is not much vomiting, the chalk mixture with a few minims of tincture of opium will often suffice. In later epidemics, undoubtedly, the dilute sulphuric acid mixture has been rather preferred, especially where there is much sickness. More effective than either in many cases, and more easily retained in cases of sickness, is a small pill of solid opium and acetate of lead in the proportion of half a grain, to two, three, or even four grains of acetate of lead. The house-to-house visitor, who of course would be a qualified practitioner, should carry such pills with him. The diet should be of a light and unirritating character; the patient should lie in bed, and have a large linseed-meal poultice applied to his abdomen; cold water should be freely allowed in quantities short of those which might excite vomiting; where that is not borne, ice is of great use.

When the stage of diarrhœa is passed, much more complicated changes and lesions have to be realised, and a wise treatment becomes increasingly difficult. It is not the least valuable part of KOCH'S investigations to have given more precise pathological definition to these changes, and to have shown us that, besides deadly collapse, with lividity, suppression of urine, pyrexia, &c., we have in a large majority of cases remarkably "severe intestinal lesions" to deal with—dark reddish-brown colour of the mucous membrane, with superficial

Digitized by Google

hæmorrhages, or the mucous membrane necrosed or covered with diphtheritic patches; the contents of the intestine being sanguinolent, ichorous, and putrescent. Our readers would do well to refer to THE LANCET of the 9th inst., p. 249. It would be folly to dogmatise on the treatment of such conditions any more than on those of typhoid fever. Immense good is done by realising the complications of the case and the possibility of doing harm by expecting immediate and instantaneous changes from vaunted or specific remedies. Opium here is out of place. Stimulants, too, can only be used with great caution. Food must be of an unirritating character. Mr. MACNAMARA recommends warm enemata of beef-tea with brandy every third hour in cases where the purging has abated. Food given by the mouth may be iced, and the powers of life must be husbanded by warmth and rest.

The difficulty in the treatment of the advanced stages of cholera will have two lessons for all sensible people:—First, that what is difficult for doctors must be much more so for those who are unlearned in disease; and, secondly, that their whole efforts should be directed to giving the profession every assistance in promoting the early treatment of cases, and diffusing general intelligence as to the laws which regulate the spread of the disease.

IN accordance with the recommendation of the Committee presided over by Lord MORLEY, the system of examination of army medical officers previously to promotion has been reintroduced into the service. We always held that the abolition of these examinations was a mistake, and therefore think this a step in the right direction. But we regret that we cannot speak in terms of unqualified praise of the regulations upon the subject just issued with the *Army Circular* of August 1st. They are divided into two sections. 1. Rules for the examination of surgeons previous to attaining the rank of surgeon-major, which may be taken at any time between their fifth and tenth year of service. The examination is to embrace (1) surgery, operative and practical; (2) medicine and pathology; (3) hygiene; and (4) duties of executive officers during peace and war, at home and abroad and at sea. There are certain exemptions from the examination which it is unnecessary to detail. But there are two very serious objections to the rules as laid down. First, it is not stated whether the examination is to be optional or compulsory; nor is any penalty attached to the refusal or neglect to undergo it. If there is any practical difficulty in applying the new rules to officers appointed under the warrants of the last ten years, it ought at least to be made clear in what manner they are to operate in the case of those now entering the service. Nor is it stated when these rules are to come into force. It surely cannot be intended to subject officers to such an examination without giving them due time to prepare for it. But the second objection appears to us a much more serious one. It is enacted that "a certificate will be required from a recognised teacher of surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator." But nothing is said of the manner in which such certificate is to be obtained. Is every officer to have a certain amount of leave, over and above that usually granted, to enable him to attend such "recognised teacher of surgery"? Is the expense of this "complete course of operative surgery" to be defrayed by him or by the War Office? And in what manner are the necessary subjects for operations to be obtained? We confess that in the absence of any explanation on these points this new rule appears calculated to inflict a serious injustice upon the junior medical officers; and we trust, in the interests of the service, that it may be either abolished or very materially modified. Unless something is done in this direction, it will probably have the effect of preventing many of the surgeons from undergoing the examination. 2. The second section of the regulations contains "rules for the examination of surgeons-major of twenty or more years' service; the examination will be optional." But the option is so far modified that until the surgeon-major has passed the examination he will not be eligible for promotion to brigade surgeon and the administrative ranks. We consider this a very fair condition, as the subjects of examination are all such as a medical officer ought to know well if he is to discharge efficiently the duties of the higher grades. They relate chiefly to the organisation and administration of hospitals and to the duties of the medical staff corps, the relations of the medical and other departments of the army to each other, field service with troops, sanitary duties in peace and war, epidemiology, and the protection of sick and wounded against pyæmia, septicæmia, and all other forms of blood-poisoning, and their treatment when they occur. The examinations are to be partly written and partly *viva voce*, conducted by an examining board, who will record the questions and answers, and forward them with all the written documents to the Director-General, without expressing any opinion as to the result. We believe that this examination for the higher grades, if properly carried out, will tend to exclude incompetent officers from positions of serious responsibility, and will operate beneficially in the interests alike of the department and the service generally. But we trust the authorities may be induced to reconsider the rules laid down as to the examination of the surgeons, and to modify them in such a manner as will remove all ground for a complaint of injustice on their part.

IT is generally admitted that the British Pharmacopœia is an eminently unsatisfactory work. It has been unhesitatingly condemned by the highest medical authorities in the country. We have over and over again urged the necessity for placing it on a more satisfactory footing. At the recent meeting of the British Medical Association at Belfast it was criticised in unmeasured terms, and a resolution was passed urging the Council "to consider with as little delay as possible what steps should be taken to ensure that the proposed new edition be brought into more complete accord with the present state of medical knowledge." A committee was appointed to further this end, and to organise means for establishing a supplemental or semi-official list of remedies the properties of which might not have been sufficiently investigated to warrant admission to the Pharmacopœia itself. This list, added to or modified from year to year, would, it was thought, form the basis of changes to be con-

Digitized by Google

sidered by the sub-committee of the Medical Committee at their periodical revision of the official publication. The scheme has excited some discussion, and several well-known authorities have published their views on the subject. Dr. FARQUHARSON, speaking of the present Pharmacopœia, expresses a hope that something may be done to bring this antiquated volume into harmony with modern usage. By this, he explains, he means not the revision rendered necessary by self-progress and the introduction of those new drugs which have established their claim to popular favour, but a "drastic and thorough overhauling of every page," and the "summary ejection of useless and superfluous articles." "Nothing in connection with materia medica," he says, "has surprised me more than the way in which many so-called remedies, which no one ever dreams of using, and which probably could not be found in case of need, are permitted to cling with the conservative tenacity of barnacles around our modern text-books." Dr. LAUDER BRUNTON endorses Dr. FARQUHARSON'S statements, and pleads for the introduction of more preparations, which shall be not only useful as remedies, but agreeable to the palate. At present, the medical man who writes a prescription is undoubtedly at a great disadvantage with one who dispenses his own medicines. The latter can remedy anything objectionable either in appearance or taste, whilst the former is almost entirely limited to the official preparations, many of which are abominably nasty. At the British Pharmaceutical Conference, held at Hastings last week, the President spoke of the necessity, long experienced, of a better Pharmacopœia, and claimed for pharmacists the right to participate in the production of this important work. He argued that they, as a body, knew more about the practical niceties involved in the preparation of medicines than anyone else, and reminded his hearers that in most countries the pharmacist was the only recognised dispenser of medicines, the practice of pharmacy being jealously restricted to those who made it a special study. This is a view of the subject deserving of careful consideration, although it is of course a mere matter of detail. What we want is a better Pharmacopœia, and if the Medical Council is unable or unwilling to accomplish the task in reasonable time, they must not be surprised if we look elsewhere for assistance.

IN conjunction with M. CHARCOT, M. PARINAUD has been engaged in studying the ocular disorders associated with disseminated sclerosis. (*Le Progrès Medical*, Aug. 9th.) The most common are muscular affections—a paralysis or paresis of the associated movements of the two eyes,—so that there is a difficulty in lateral motion and convergence. Thus, if the patient looks to the right or left without moving the head, the corneal margin does not reach the canthus, and the pupils tend to return to the middle line, owing to fatigue of the muscles. Nystagmus interferes with this observation, and, as both eyes are affected, there is no appreciable strabismus. Paralysis of convergence is readily determined. Diplopia is a frequent symptom, especially at the onset of rapid cases, disappearing after a month or two, either in reality or apparently, but it is less marked than in monocular paralysis. Nystagmus, the most important symptom, is due to the paralysis of associated movements, being excited by attempts at fixation, and more pronounced when the eyes are turned to the right or left. The nystagmus is not apparently related with the degree of paralysis; it is more likely dependent on an incomplete paralysis arising from a lesion of the centres governing associated movements. The vague faccial expression so characteristic of this disease is accounted for by this derangement in ocular movements, for the physiognomy depends largely on the remarkable synergy that enables the eyes to travel together in all directions, their axes being constantly changed for accommodation to various distances. Ordinary paralyses of peripheral origin are rare; but M. CHARCOT has seen cases of ptosis. As to the iris, slight inequality of the pupils is not infrequent in the early stages, especially when the eye is at rest. Later, myosis is marked; but in either state the reflex contractions to light and accommodation are preserved—a point of importance in the diagnosis from tabes, of which the Argyll-Robertson pupil is one of the earliest and most characteristic signs. These pupillary reflexes may even be exaggerated in disseminated sclerosis, so that the pupils contract extremely, even if already myotic. It is held that this suffices to dismiss the idea of tabes from such a case, and to suggest disseminated sclerosis. The myosis of tabes with early abolition of light-reflex, and sometimes even of contraction for accommodation, is a kind of paralytic myosis; that of sclerosis with preservation or exaggeration of the same reflexes may be regarded as a spastic myosis. The analogy of these ocular reflexes with the tendon-reflexes in these two affections is therefore striking. As regards the optic nerve, M. PARINAUD points out that amblyopia occurs in this disease under three forms. In many cases it arises slowly; visual acuteness is about the same in both eyes, and the field is normal. There is a certain amount of dyschromatopsia for red and green, often an early and well-marked symptom. In many cases there are no papillary changes, but when advanced the papilla may be pale, especially in its temporal half. In the second form amblyopia develops rapidly, and leads to absolute but transient blindness. This may pass away to such a degree that the patient can read fine type; but the colour-blindness persists, the visual field is contracted, and the optic discs remain notably white. M. CHARCOT has never seen a case of persistent blindness, although the atrophy of the optic nerve may be quite obvious; and this affords a contrast to tabetic atrophy. In the third form the amblyopia and nerve change is unilateral; but this is rare, and is probably due to sclerosis of the nerve itself, the bilateral variety being referable to central lesion.

WE have had frequent occasion of late to animadvert on the unsatisfactory state of the law relative to private lunatic asylums, and we have observed with satisfaction in the signs recently forthcoming that the forbearance of the public in this particular is reaching its limit. But whilst fully alive to the importance of not relaxing our efforts in this direction, we cannot shut our eyes to the fact that in a far different quarter—that, namely, of the public asylums—a state of things is arising serious enough to justify grave uneasiness, and even alarm. The tendency of late years has been for these institutions to be ever growing larger and expanding their borders, until they are assuming proportions altogether unwieldly; and we see cases in which from 1500 to 2000

Digitized by Google

insane individuals, *supposed to be patients*, are congregated under what is practically one roof, and under the care and control of one medical man.

Now if institutions of this magnitude are intended solely for the *care* of the insane, we have nothing to say against them; but, on the other hand, considered as *curative* establishments, their constitution is a delusion and a snare. To say that a certain number of recovered individuals are turned out annually from these institutions is beside the mark. Thanks to the *vis medicatrix naturæ*, cases will often recover when but a minimum of care and attention is bestowed on them. It does not admit of either question or dispute that from the large amount of administrative work necessarily devolving on the medical head of one of these huge establishments his medical functions are practically in abeyance. It is certainly little to the credit of the English lunacy system that the enormous mass of material that annually passes under the eyes of the medical staff of the asylums is almost wholly unutilised.

In saying this we give the explanation of the comparative stagnation of the special department of medicine under consideration, for whilst other branches of the art are advancing by leaps and bounds, psychological medicine, if not altogether stationary, manifests at best but a lame and halting progress. Let us not be misunderstood: we consider that the English county asylums are admirable institutions for the *care* of the insane, and in this regard reflect credit on their management; but as *curative* establishments they are by no means to be looked upon with equal favour. In truth, the great thing needed is the separation of the cure department from the care department of the insane; for whilst for the latter object large institutions are not harmful, and may be necessary, the establishment of small lunatic hospitals is in many ways imperative for the former. Such institutions officered by able and earnest medical men would doubtless before long yield abundant fruit. The only possible objection to this view—the economic one—has not, we think, any weight. Granted that these small curative establishments might be more expensive than the average county asylums, the extra expense incurred might be, and would be, fully compensated, and perhaps more than compensated, by the saving effected on the chronic cases in the asylums reserved for their care. Such a division of labour would, we entertain no doubt, have far-reaching beneficial effects, and be highly conducive to the welfare of the patients; and in the long run we make no question but that many an individual might be thereby rescued from being a burden on the rates for a period bounded only by the term of his natural life.

AMONGST the Acts of Parliament to which the Royal assent was given on the 14th inst. were the following:—The Cholera Hospitals (Ireland) Act; the Canal Boats Act; the Criminal Lunatics Act; the Disused Burial-grounds Act; the Cholera &c. Protection (Ireland) Act; the Public Health (Ireland) Amendment Act; the Public Health Officers Act; and the Brighton Improvement Act.

ON the 16th inst., a patient, while in a delirious condition, escaped from the temporary hospital for small-pox cases at Crewe. After five hours' search he was discovered hidden in some corn. He was naked at the time of his escape, and died on the 20th from the effects of disease and exposure.

Annotations.

"Ne quid nimis."

THE MEDICAL COUNCIL.

THE Medical Council is summoned to meet on the 6th of October, chiefly to elect a President, Sir Henry Acland's term of office having expired. It is possible, too, that by that time the English Colleges may have prepared a scheme, or may reproduce the old one, for a conjoint examination, and may ask the Council to sanction it. We shall revert to this subject before the meeting of the Council.

OPENING OF THE FIFTH INTERNATIONAL CONGRESS OF HYGIENE.

ON the 14th inst. the fifth international gathering of sanitary reformers was opened at the Binnenhof or First Chamber of the States General of Holland. Our correspondent will send us from the Hague some details of the proceedings, but we have already received the summary of the various reports which are presented as the basis of discussion. Thus, for instance, Dr. Corradi of Pavia will seek to demonstrate that we may admit the possible contagion of phthisis, but that transmission by clothes, rags, &c., is not yet proved. Cohabitation is the most likely, if not the only, means of contagion. Dr. Vallin of Paris has a report on the spread of tuberculosis by infected meat and milk, which he considers may occur unless the cause of infection is destroyed by exposure to great heat in cooking. Dr. Napias, as usual, appears as the champion of the working classes, claiming better legal protection for them against unwholesome industries and unhealthy dwellings. A great number of papers will be read by Dutch medical authorities on Over-pressure in Education, the Influence of Life Insurances on Infant Mortality, the Effect on Climate produced by the Destruction of Forests, and other topics. As yet no mention is made of Cholera, but it will be found almost impossible to exclude this "burning question" from the debates, and naturally the drainage of towns, notably Paris, will receive a large share of attention. The Congress will close its proceedings on Wednesday, the 27th inst. For Sunday next the Rhine Railway Company has placed a special train at the disposal of the members of the Congress, to take them to Rotterdam, Feyenoard, Dordrecht, and Moerdijk. There are entertainments for every evening, and the town of the Hague gives a reception to the members of the Congress at the Palace of the Arts and Sciences. Altogether, the Dutch will not fail to prove themselves worthy of their high reputation for hospitality.

REGISTRATION OF LODGINGS.

NEVER was this precaution more necessary than now. In consequence of the cholera scare and the clumsy and erroneous quarantine precautions taken by our neighbours generally, the watering-places and "health resorts" on this side of the "silver streak" are crowded, and it may be assumed that hygienic conditions are often seriously neglected. It would have been far wiser, in a precautionary sense, if the great bulk of English people had stayed at home this year, instead of exposing themselves and their families to the exceptional perils of towns and villages in which the one eager desire is to make hay while the sun shines, regardless of the most obvious dangers and careless of results, provided only that they can contrive to take the largest possible advantage of unusual if not unprecedented opportunity. Medical officers of health would do well to look into this matter at once, and, as some have had the courage and honesty to do, institute a system of special certificates, even

Digitized by Google

without the sanction of authority. Those who recommend sickly persons and families to hasten to these overcrowded places ought to share the responsibility of the advice they give with the local medical officers, by taking the trouble to ask the advice of these local men as to the particular hotel or house to which they send the persons who have consulted them.

ALCOHOLIC PARALYSIS.

THE current number of *Brain* contains an interesting account by Dr. Dreschfeld of Alcoholic Paralysis. He distinguishes two forms of the affection, the one being marked by ataxic symptoms, chiefly occurring in males, and subsiding on discontinuance of the alcohol. He thinks that the history of such cases of alcoholic ataxia, together with the absence of many of the ordinary symptoms of true dorsal tabes, suffice to determine their etiology. Moreover, tabetic symptoms—especially the absence of tendon reflex and the lancinating pains—are sometimes seen in the more typical cases of alcoholic paraplegia. This latter type is, he says, more frequent in females who have been addicted to alcoholic excess. The symptoms begin more or less acutely, and consist of sensory disorders, as hyperæsthesia of the lower limbs, sometimes with hyperalgesia, and often with lancinating pains and spinal tenderness. Anæsthesia or retarded sensibility and analgesia may follow. There is more or less motor paralysis, mostly of the lower but sometimes attacking the upper extremities, with diminished superficial reflexes and absence of tendon-reflex. Redness of the feet, hands, and other parts indicates vaso-motor disorder. Cerebral symptoms—as insomnia, restlessness, more or less delirium, and hebetude—may arise in the course of the disease, and are often the cause of death. As to prognosis, some cases which are early cared for recover; others recover for a time and then relapse; in others the course is steadily downward, death ensuing from cerebral symptoms, from exhaustion, or some intercurrent affection. Dr. Dreschfeld gives details of a well-marked case, which was readily diagnosed. It proved fatal, and at the post-mortem examination pulmonary and renal tuberculosis was found, but no lesions in the spinal cord. The peripheral nerves (the sciatics, musculo-spiral, and anterior crural were examined) showed degenerative changes, breaking up of the myeline, and in many places of the axis cylinder also. The condition is, then, one of peripheral multiple progressive neuritis, and can be distinguished mainly by its less acute course, and limitation of paralysis to the extensors, as well as by the more marked hyperæsthesia from the non-alcoholic progressive multiple neuritis described by Leyden, Strümpell, Pierson, and others. Its resemblance to lead paralysis was pointed out by Lancereaux, and Dr. Dreschfeld concludes by mentioning two cases of visceral neuralgia attributed to alcoholism which have some analogy to lead colic.

FEEDING OF INFANTS.

As a good working rule, it cannot be denied that infants under the age of seven months should take nothing but milk. Further, it must also be owned that some infants thrive though a departure be made in the direction of farinaceous additions to their diet; but the proportion of those who are able to bear deviations from the natural food must be very small. So that he who maintained that such farinaceous additions were innocuous would be under the necessity of proving his assertion. It appears to us that the matter lies in a small compass, and may best be explained by analogy. Some individuals can get through more work than others, their reserve force being greater. So it is with an infant's digestion. Human milk is that which nature has found to be best for infants generally; and if that cannot be obtained, other fluids artificially prepared must be substituted for it, closely resembling human milk. No starchy additions can be made without taxing the reserve forces of infantile digestion. Generally the tax cannot be met, and the insolvency of digestion is shown in the production of rickets. It must follow, therefore, that even those infants who do thrive when amylaceous articles are given, do so at an expense and loss which may not be evident, but which is nevertheless real. Dr. Keating has come to the following conclusions from some observations made on the salivary digestion of starch by infants:—The saliva of some infants possesses the property of converting starch into glucose. The age of the infant cannot be taken as an indication of this property of its saliva. When such a condition is found to exist, a small quantity of well-prepared farinaceous food is valuable as an element in the diet. (This proposition we should be disposed to take exception to.) An examination of the stools of children so fed would be a guide as to the quantity of starchy food to be used, and when farinaceous food is employed, slow feeding is probably preferable to the use of the bottle.

SHOP EMANCIPATION.

THE conviction that shop labour no less than factory labour needs regulation is happily gaining ground. An able article by Lady Manners in the *National Review* takes up the principal points on which the present system of shop service errs. The practically unrestricted duration of daily work is usually regarded as comprehending the essence of the evil which it is sought to remedy. Roughly it does so, but associated faults are numerous, and from their nature cannot but aggravate greatly the bad effects of mere fatigue. The work of shop assistants may not, as a rule, be so severe in its muscular strain as that of factory *employées*, but it implies mental effort of quite equal and often greater tension and diversity. Again, the conditions under which work is done are usually anything but satisfactory. Under the best management ventilation is apt to be faulty in many such establishments. A space originally insufficient to contain the air-supply of twenty or thirty daily inhabitants, and ten times as many regular frequenters, cannot with any ordinary provision for renewal of its atmosphere be expected to feed the combustion of so many pairs of lungs, reinforced, it may be, by a brilliant array of gas jets burning in full flame. The heat of such rooms is in itself at once a test of their impurity and an independent cause of mischief. As regards meal-times, it is well known that the dinner "hour" is commonly a fable. In some houses the term "meal-time" has hardly any meaning during a busy season. Arrangements for other necessary calls of nature are sometimes so awkwardly designed that decent attention to these is not possible. The unclean overcrowding of young men or women in their dormitories is an old evil. So is the want of seats in shops, where these might well be allowed were master tradesmen willing to be as frank as they are facile towards their customers. It is not necessary to tell medical men that early disease and death are frequent under these conditions. Each of them has seen the vested capital of the shop attendant—health—again and again merged into the growing revenues of his employer. The remedy which is asked for this state of things is that a term equal to the average period of factory work, fifty-six hours per week, meals having been allowed for, should be assigned to shop labour. This is not too much to ask. In the case of women it is, we think, too little. Employers and customers, particularly poor customers, it is hoped, will endeavour to put an end to the metropolitan habit of shopping late, and the public is appealed to in support of the whole project of reform. We strongly recommend the public to listen to that appeal, and we hope that

Digitized by Google

all that social agreement can do may be accomplished by that means. At the same time, the question of shop labour in all its bearings appears to us much too large for settlement in this way. State legislation, which we deprecate wherever it can be done without, is here necessary. It has been successfully applied to the regulation of factories, and there is no reason why it should not be used with equal success to correct the very faulty righteousness of counter traffic.

THE PATENT MEDICINES STAMP ACT.

THE *Saturday Review*, in an able editorial on this subject, points out that there are few things more to be regretted in connexion with the Session just closed than the failure of the Government to put the Patent Medicines Stamp Act on a more satisfactory footing. "There is of course a small loss of revenue to be apprehended, but there are a hundred less harmful ways in which a similar sum might be raised. Mr. Childers stated in the House of Commons that the stamp at present brings in £160,000, and that he could hold out no hope of a repeal of the tax. This, if correctly reported, was curious language to use, the more so as he went on to say that he had applied to the Board of Inland Revenue for information on the subject, which he promised to study. The object of studying with care the operation of a tax which he holds out no hope of repealing is not very clear." We should concur in the justice of these strictures if we were satisfied that the utterances of the Chancellor of the Exchequer had been accurately reproduced. We have reason, however, to believe that Mr. Childers, if not incorrectly reported, was at all events reported less fully than he might have been. It appears that after he had replied to Mr. T. P. O'Connor, he was asked by Mr. Warton if the Government next session, or next session but one, intended to carry out the promise they made on March 26th, to bring in a bill dealing with patent medicines. Mr. Childers said he had taken no part in the discussion on the subject, but thought he might give the promise asked for. We are glad to find that the necessity for active interference is recognised by the Government, and we look forward with confidence to the repeal of the Act. The subject has been warmly discussed by all classes of society, and there is a general consensus of opinion that a question which concerns so vitally the health of the people cannot be dealt with too promptly.

ERYSIPELAS AFTER VACCINATION.

AMONG the accidents of surgery is erysipelas—an accident in many cases avoidable and avoided by surgical forethought, but one arising from so many different and often exceptional circumstances that it does not seem possible that the strongest concentration of human skill will ever banish it from the list of diseases. Nay, its very standing as a disease has reference rather to the degree than to the type of change which it indicates. Through the term erythema we can trace a generic development from the blush of emotion or the rosiness which borders a healthy wound to the tense and even suppurative hardness which we usually name and treat as erysipelas. This variation of type depends upon variety in causation, and the force and kind of the resulting change reflect the character of its stimulus. It will readily be admitted by all medical authorities that that two chief groups of such causes exist—that in which mechanical irritation is the prevailing feature, and that in which aceptic forces are at work. In aid of these there often comes the habit of body of the person attacked. The under-fed or improperly fed, the overworked, the relaxed and flabby types—in short, any in whom health means less than vigour—possess this constitutional proneness. There is abundant and daily evidence that dangerous degrees of erysipelas may proceed from almost any surface injury, as well as from deeper faults of vital action. The pin-scratch has no immunity which the amputated stump has not. In either case, dirt, friction, bad ventilation, and other equally common conditions may introduce this unwelcome complication. Much has been made of erysipelas after vaccination, and a feeling has been created by prejudiced and half-informed people against that measure on the ground of this occasional sequel, which is not its consequence. No candid mind can fail to see that there are numerous circumstances in the lot of children, especially of poor children, which help to determine inflammation at the seat of a pustule or of any irritable sore. The child may be unhealthy; the home may be unwholesome; the parents or the child may be uncleanly; the arm may have been rubbed by one of the shields so commonly in use, or clothed in some poisonous aniline-dyed sleeve such as the small draper can always find for a poor customer fond of colour. In these and many similar ways fault creeps in, but careful and thorough vaccination cannot, and does not, furnish a sufficient cause for fatal erysipelas. Much of the misconception on this point has arisen from a confusion of cause and effect, of *post hoc* with *propter hoc*, which unbiased reflection alone can remove. In this question, as in every other, judgment, not prejudice, must inform public opinion in order that neglect may receive its proper name and punishment, and vaccination may not be saddled with discredit which does not belong to it.

"KILLED BY LIGHTNING."

THE lamented death of the Earl of Lauderdale from the effects of lightning has served to emphasise the danger to life that lurks in one of the grandest and most entrancing manifestations of nature—a thunderstorm. In the majority of instances no amount of forethought or care can save the victim from the impetuous and capricious influence; and yet we think that not a few fatalities might be avoided if people only possessed the most rudimentary knowledge of electrical science, and the presence of mind to act upon such knowledge. But, in truth, there is much that seems mysterious in the lightning flash and its attendant phenomena. The brilliant presence and the wondrous sequel inspire the imagination more than the judgment. Poets and sages have clothed the zigzag writing in the air with attributes that are many of them only links in the chain of conditions of which itself is one, and have erred in assigning to the comparatively harmless thunder the dire effects of the momentary passage of the electric fluid. In one of his "Hebrew Melodies," Lord Byron has written: "As fall the oaks at once, and blasted by the *thunderstroke*." The subject of electro-dynamics is very abstruse, and yet it requires no great acuteness of intellect to enable one to grasp the main facts relating to the correlation and mutability of forces. It may not, however, be easy to demonstrate to the unscientific mind how an electric current displaces the atmosphere and causes those marvellous successions and intervals of sound which in the aggregate are known as thunder; how it is rendered visible as a flash of light, or is transmuted into electrolytic action, decomposing the most stable chemical compounds; or, lastly, how it is converted into an outburst of mechanical violence of uncontrollable and almost immeasurable power. The familiar exhibitions of the workings of Nature's laboratories may be utilised for instruction and guidance. Had George Henry Mitchell, killed by lightning on Saturday week last whilst seeking shelter under a tree, been aware of the danger he was incurring by placing his body in close proximity to an imperfect conductor, he would have preferred a good drenching in the open meadow to the treacherous protection

Digitized by Google

he sought from the storm. In this man's case the face was blackened, the hair on the face and head singed, and the left tympanum ruptured; his hat was torn, the laces of his boots charred, and in the instep of each boot a large rent was made. Results very similar to those last mentioned may be seen in the museum of St. Mary's Hospital, here in that instance the patient recovered. In Lord Lauderdale's case, a deep wound was inflicted on the forehead, scorched lines indicated the path taken by the electric current, whilst his lordship's watch and chain were fused. It is a well-known fact that the course of the superficial vessels and nerves is occasionally mapped out with tolerable accuracy. The blackening is partly due to simple burning, partly to reduction of the oxyhæmoglobin of the blood. It was formerly supposed that the blood of animals killed by lightning remained quite fluid, but such is not the fact; the coagulation, nevertheless, is imperfect.

ALLEGED CURE FOR HYDROPHOBIA.

As far back as 1865, Dr. Buisson, a respected correspondent reminds us, wrote in the *Salut Publique* of Lyons an article claiming to have discovered a remedy for hydrophobia. The Doctor is said to have himself been inoculated with the virus of rabies by means of the saliva from a patient suffering from the disease; the saliva impregnating a handkerchief having come in contact with a slight abrasion on his left index finger. Nine days after the accidental inoculation Dr. Buisson began to suffer from symptoms referable to hydrophobia. When this stage had been reached, vapour baths at a temperature of 52° C. were had recourse to, not with the intention of cure, but it is said with a desire to produce suffocation. According to the account given, strange to say, the whole of the symptoms disappeared and never recurred. Dr. Buisson declared that after his recovery he attended eighty individuals who had been bitten by mad dogs, and never lost a single case. When an individual has been bitten by a mad dog, he must for several successive days take a vapour bath. This procedure is spoken of as the preventive remedy. When the disease has declared itself, one vapour bath alone is required, the temperature being rapidly raised to 37° C., and then more slowly to 63°. The patient must be strictly confined to his chamber until the cure is complete.

THE "SLUMS" OF NEW YORK.

On a recent occasion we alluded to the new law affecting the drainage and salubrity of the tenements occupied by the New York poor. Unfortunately these regulations, though excellent and productive of beneficial results so far as new buildings and respectable lodgers are concerned, cannot prevent the fearful overcrowding, squalor, poverty, and dirt that have for long existed, especially on the Manhattan Island. A lengthy report, accompanied with a sensational illustration, was recently published by the *New York Herald*, describing the condition of the New York poor as equal to what may be seen in the worst quarters of London. In Manhattan Island the number of poor tenements has increased from 14,494 in 1869 to 21,163 in 1881. The immense size of the houses renders their ventilation extremely difficult, and the *Herald* report describes "the intensity of the pollution of air in these buildings as inconceivable." Nothing can surpass the "impurities found in such a place as Gotham-court, which for thirty years was filled with cases of contagious disease, and where a census taken by Dr. Elisha Harris in 1859 showed 250 sick out of a population of 500, including typhus fever on every floor, and numerous cases of typhoid fever, measles, scarlet fever, small-pox, and diphtheria." The new and model tenements are also reported to be almost as offensive as the worst rookeries, in consequence of the neglect on the part of the tenants and lack of supervision by the landlords. In New York, as in London, the Italian, Irish, and Poles are the most difficult to train to ideas of order and cleanliness. Altogether, the main facts and difficulties seem to be much the same on both sides of the Atlantic. The Americans, however, have a good law, and we trust they will succeed in securing its rigorous application.

RELAPSING FEVER.

Dr. Vandyke Carter has published a *brochure* comprising observations on relapsing, or, as he terms it, "spirillum fever," made in Bombay subsequent to the appearance of his work on the subject in 1882. He describes examples of sporadic cases, and of others occurring in the form of restricted epidemics, all the cases presenting the usual features of the disease; and his former conviction was also confirmed as to the symptomatology being more diverse than is often supposed. The mortality, so far as could be ascertained with certainty, of these cases was 6·6 per cent. Nothing new was learnt as to treatment, the high pyrexia being quite uncontrolled by sodium salicylate and resorcin. He lays stress upon the importance of arriving at an early diagnosis, and the great value of the detection of the spirillum in the blood, a test which he recommends should be adopted in all "outbreaks of epidemic or endemic fever of doubtful character occurring in the districts and jails of this country." He believes this to be the pathognomonic sign, and its presence to be sufficient to establish diagnosis in a doubtful case, whether the relapsing character of the fever be present or not. Failures to detect the spirillum, on the other hand, do not positively negative a diagnosis, since the microscopic investigation requires naturally special care and attention. The importance of some definite means of distinction from other types of fever which prevail in India is self-evident, and Dr. Carter does well to insist on the application of all means to this end. Dr. Carter adds some interesting data concerning the gradual decline of the epidemic which began in Bombay in 1877, and mentions that the persistence of the disease cannot be attributed to a continuance of distress and famine. It would seem rather that it had become naturalised or endemic, and evidence of contagion was strong in many cases. Speaking of the general course of epidemics, he compares their character to that of a conflagration, "which begins, extends, and becomes extinct proportionately to the amount, state, and location of inflammable material encountered during its existence"—a far apter comparison, he thinks, than the ordinary conception of a "wave" or atmospheric current.

"BURYING CHOLERA PATIENTS ALIVE."

It is not so much undue haste as inexcusable carelessness that must be blamed for the premature burying of persons who are not really dead. Such heedlessness as alone can lead to the commission of this crime is not a shade less black than manslaughter. We speak strongly because this is a matter in regard to which measures ought to be at once taken to render the horrible act impossible and to dismiss all fear from the public mind. If it be a fact, as would seem to be indisputable, that during the last few weeks there have been cases—we will not attempt to say how many or how few—of burying alive, a scandal and a horror, wholly unpardonable in the last quarter of the nineteenth century, have to be faced, and the sooner the full truth is known and rules of safety established the better. Let it be once for all decided that measures shall be taken to ascertain the fact of death before burial. Why not revert to the old practice, and *always* open a vein in the arm after death, or pass a current of elec-

Digitized by Google

tricity through the body before the coffin is finally screwed down? It may be held that these unpleasant resorts are unnecessary. We do not think they are. In any case enough is known of the *possibilities* of "suspended animation" to render it unsafe to bury until the evidences of an actual extinction of life are unmistakable; and, as it is impossible to wait until decomposition sets in in all cases of death from infectious disease, it would be prudent to adopt what must certainly be the least of evils.

DISINFECTION AND DEODORISATION.

WE have received certain papers from Messrs. Fearenside and Baynes as to a patent automatic disinfecting and deodorising apparatus, which can be used in connexion with waterclosets, urinals, water-carts, &c., and which is so designed that any given quantity of a disinfecting fluid can be mingled with the water and be automatically delivered whenever either of the appliances referred to comes into use. Mechanically the arrangement is ingenious, and wherever the regular mingling of a fluid disinfectant with any water becomes necessary it will be useful. But our doubt as to the value of this and allied appliances is twofold. If a waterCloset, for example, be foul, its filth will certainly not be "disinfected" by means of such an arrangement. Disinfection must be regarded as meaning the destruction of matter capable of conveying infection, and in the present state of our knowledge as to what constitutes the poison of the infectious fevers we cannot speak of disinfection apart from the destruction of all the organic matter in which the infection may lie hidden, and it is certain that no occasional flushing with water containing a certain quantity of any of the ordinary so-called "disinfectants" attains this end. Then, again, if a watercloset does really stand in need of such occasional chemical flushings, it may be taken for granted that the apparatus is in fault, being one permitting the retention of contents or being otherwise favourable to foulness. The remedy is to get rid of the faulty contrivance, not to attempt to deal with it by disinfecting fluids. In so far as the apparatus facilitates deodorisation it may have important uses, especially in connexion with urinals and street watering, but even then we should prefer to see the removal of the conditions which lead to offensiveness, rather than the attempt, however successful, to deal with them by an ingenious method of deodorisation.

SAFETY FEVER AMBULANCE.

HAVING been for some time past impressed with the idea that ambulances as at present constructed must be a source of danger to the public, Dr. Gayton, medical superintendent of the North-Western District Hospital, Haverstock-hill, has recently had a carriage so altered as to do away with, or at least modify, such danger. To those acquainted with the ambulance carriage at present in use, it must be apparent that the open windows and louvre-shutters readily permit a free egress to infectious matter from patients; and should a susceptible person be near such a source of infection—when, for instance, the carriage stops at the gates of a hospital till admitted,—such a person runs a decided risk of "catching the fever." In his ambulance, Dr. Gayton has replaced the louvre-shutters and a portion of each window by a double layer of perforated metal, between which wool, lint, or other suitable material, impregnated with some recognised antiseptic, can be placed. One of the layers of metal is so arranged as to permit of the old wool or lint being readily removed. With this arrangement it becomes necessary to have some special means for ventilation, and in the new ambulance used is made of Tobin's shaft, modified as follows: The shaft is horn- or trumpet-shaped, with the small end placed vertically within the ambulance; in this end is fitted a plug consisting of a double layer of the perforated metal, with antiseptic material interposed. The larger end of the shaft opens externally just below the driver's seat, with the opening so placed that when the ambulance is in motion the air blows directly into it. Two shafts are provided for each ambulance, placed one on either side of the driver's legs.

THE BRADSHAWE LECTURE.

NOTWITHSTANDING the unfavourable effect of the temperature and other peculiarities of August in London, and we may even admit of some peculiarities in Dr. Philipson's elocution, it must be acknowledged that Sir W. Jenner could not have made a fitter selection for the Bradshawe Lecture than Dr. Philipson, and that the lecturer could not well have chosen a subject more congenial to the character of Bradshawe or to the designs of his widow in founding the lecture, than the Pathological Relations of the Absorbent System. This great system of vessels and glands, with all their hidden and quiet operations, are apt to be forgotten but for such expositions as Dr. Philipson's, and those of Dr. Curnow in his capacity of Gulstonian lecturer in 1879. Practitioners who consider that there are probably a thousand lymphatic glands in the body, that the lymphatic vessels are the main agents in the transmission of the gravest forms of disease, and that the fluid discharged from the thoracic duct of man in twenty-four hours is estimated at six or seven pounds, can scarcely fail to realise more fully the importance of this system and its pathological conditions, which will be found well described in this Bradshawe Lecture.

SANITARY CONDITION OF CALCUTTA.

THE memorial to the Lieutenant-Governor of Bengal from the European residents in Calcutta has already led to important action bearing on the sanitary condition of the city. In a letter addressed to the chairman of the municipal corporation, the secretary to the Government informs him that the Lieutenant-Governor, after a careful inquiry into the statements of the memorialists and a review of the action which has been taken by the commissioners in connexion with the required sanitary improvements, is of opinion that it is fully established "that the past and present action of the commissioners for the sanitation of Calcutta is inadequate." And he is of opinion that it is no less clear that the outbreak of disease in March and April might have been mitigated had proper measures been adopted to improve the condition of the unhealthy portions of the city. "While the mortality from cholera was less than 5 per mille per annum in the Park-street Section, it was 46 per mille in Jorabagan, 36 per mille in Burrabazaar, 31 per mille in Coomertolly, and 25 per mille in Jorosanko and Colootollah." After pointing out how the commissioners had neglected to adopt the advice given them by their officers on the subject of the removal of undoubted sources of disease, he adds, "Nothing can be more certain than that, had the commissioners taken more vigorous and determined action to carry out the Lieutenant-Governor's recommendations upon this point, the virulence of the late outbreak would have been greatly mitigated." Recognising, however, that one of the great difficulties in the way of sanitary reform has been the want of a clear understanding of what has been required, the Lieutenant-Governor has decided to appoint a committee, consisting of the chairman and two members of the corporation, two medical officers, an engineer officer, and a non-official European gentleman to be nominated by the Government, whose duty shall be "to draw up (1), for each section of the town, a complete scheme for the reclamation of bustees, the filling up of tanks, the provision of water-supply, surface

Digitized by Google

drainage, and the like; and (2), for the whole town, such a scheme of structural improvements in the way of opening up new streets and straightening or enlarging existing streets, as may come within the limits of the probable financial resources of the corporation." It is to be hoped the corporation will join cordially in this work, but if not it seems pretty certain that the Lieutenant-Governor will take steps to carry out the requisite sanitary measures independently of them. The composition of the committee appears to be very satisfactory; it is not too large to work well and quickly, and its recommendations are likely to be such as may be insisted upon by the Government and carried out efficiently with the support of the leading members of the European population. The action of the Lieutenant-Governor must commend itself to all who take an interest in the physical well-being of the citizens of Calcutta.

TABES DORSALIS.

THE subject of locomotor ataxy is one which has perhaps engaged more attention from clinical observers than almost any other affection of the nervous system. The remarkable variations in and concomitant appearance of symptoms that occur in tabes seem to afford endless scope for inquiry. One of the most recent contributions to the subject is that of Dr. O. Berger, in a paper read before a Schleswig scientific society. Basing his conclusions upon the clinical features of the disease, and thereby following in the wake of Charcot, Leyden, Buzzard, and so many others, he affirms that tabes dorsalis may issue fatally without having presented any ataxic symptoms in its course; and he thinks it probable that such exceptional cases depend on the limitation of the anatomical lesion to particular tracts of the posterior columns. In the majority of cases the existence of lightning pains forms a valuable aid in diagnosis, which is further strengthened by the presence of Westphal's symptoms and the Argyle-Robertson pupil. In many cases the early occurrence of gastric crises, ocular paralysis, uncertainty of gait, &c., confirms the diagnosis. The initial neuralgia may present the character of a severe migraine. Lastly, he believes that much significance is to be placed on vesical derangement without obvious local disease.

TROPICAL HEAT IN ENGLAND.

WE have been experiencing exceptionally high temperatures both in the sun and in the shade. It is not surprising that sudden deaths have occurred, or that strong men have been overpowered. In this country, with its proverbially variable climate, the native organism is so developed as to possess a considerable faculty of adaptation to the changes we are accustomed to encounter—that is to say, to which we are habituated as individuals and as a race. The typical English "body" is furnished with a heat-producing and regulating apparatus, which is far better able to meet the demands made upon it by extremes of atmospheric temperature than is the similar apparatus of an average Indian or a Laplander. This is abundantly proved by the fact that the able-bodied Briton can live in the tropics or in the immediate vicinity of the North Pole if he be not wantonly deprived of his lime-juice. It must, however, be remembered that the majority of the population are not able-bodied; and it must needs happen that, when, relatively, excessive heat visits us, a large proportion of the population are severely tried. The tolerance of inordinate heat requires a faculty, first, of quickly "damping down" the fires within, and, second, of as quickly opening up the evaporators, radiators, and disseminators. In plain words, we must diminish the oxidising process, and at the same time—which is difficult—so determine the blood to the surface and establish a discharge of heat by evaporation as to preserve the mean of health (about 98·6–8) in spite of the sudden rise of external temperature. The diverse experiences of any dozen persons taking a Turkish bath for the first time in their lives, or much out of their habit, would suffice to show how difficult it is to avoid internal congestions, even under conditions the most radiative, in a highly heated atmosphere. We as a nation can bear sudden heat better than almost any other people, but it taxes us heavily, and many individuals must succumb. Possibly by the time this reaches the reader it may be "winter" with us again; but if the heat *should* persist or return, care should be taken to minimise the strain cast on the multitude by such obvious changes of rule in public and private workshops as shall give the weary labourer—especially if he be exposed out of doors—a period of rest during the heat of the day, such as he would enjoy if he were in form, as well as in fact, a dweller in the tropics.

ISOLATION ARRANGEMENTS AT CANTERBURY.

THE Canterbury corporation have once more, by a majority of one, decided not to provide themselves with means for isolating infectious diseases. The scheme had at last come down to the purchase of a hospital tent; but even this tentative measure has been set aside. If the decision arrived at meant that the corporation intended to commence the erection of some permanent building, however small, it would be one to be commended, for tents are not adapted to the colder months of our climate, and in point of site, sanitary arrangements, means of cooking and administration, they need much the same requirements as a brick pavilion. But we fear Canterbury is waiting for its horse to be stolen before it goes to the expense of purchasing a key. The individual members of the corporation probably act very differently as regards their own private interests, and take care to insure their premises against fire, annually paying the necessary premiums without so much as a grumble, rather than wait for a fire. The principle involved is the same, and many an authority, under the influence of a prevailing epidemic against which it has not provided itself, has had to pay far more than the accumulated annual rates which would have been necessary to provide a hospital. The action of individuals and that of collective bodies, however, often differ materially.

NORTH-WEST LONDON HOSPITAL.

IT will be remembered that after the resignation of the entire medical and surgical staff of the North-West London Hospital, the committee appointed delegates to confer with three representative members of the profession, for the purpose of framing new rules for the conduct of the hospital. We learn that rules have been agreed upon which we trust will be found to satisfy the just requirements of the profession and the public. The rule enabling three members of a committee to form a quorum, to which strong objection was taken, has been so altered that a quorum can only be formed when there are at least three members present in addition to the lady founders of the hospital.

SHIP SURGEONS.

ATTENTION is again drawn to the question of surgeons on the Transatlantic passenger steamers. The immediate occasion is the alleged death of a lady from heart disease after several days of severe sea-sickness, during the whole time of which, it is stated, neither the ship surgeon nor the stewardess visited her. The publication of this case, which is to come before the courts of law, has elicited many complaints as to the qualifications and services of ship surgeons, and correspondents have taken the trouble to publish the ages of the surgeons in the Transatlantic lines. We can make no comment whatever on the case mentioned also

Digitized by Google

until the actual facts have been elicited by the lawyers; but we must support a body of men who discharge difficult duties for the most part well, and often under great drawbacks. The appointments are such that it is impossible to expect middle-aged and experienced practitioners to hold them; but the companies can readily command the services of surgeons for longer periods by offering more liberal remuneration, and especially by giving them proper authority over all the sanitary conditions in the ship. It must not be forgotten, too, that the subjects of sea-sickness, for which, after all, medical skill can do so little, are very likely to cast upon surgeons blame which should rest upon themselves, the arrangements of the ship, or upon the sea itself.

THE HOSPITAL SATURDAY FUND.

AN admirable circular has been addressed by Mr. Morley the president, and Mr. H. N. Hamilton Hoare, the treasurer, of the above fund, to employers of labour, foremen, and others, setting forth the ease with which, by a small effort, the working men of London might add enormously to the resources of the London hospitals and dispensaries. We quote one paragraph, which is very reasonable, and is much in the line of our constant pleadings on this subject:—"There are in London at least 1,000,000 of working people who could afford a halfpenny per week each towards the support of hospitals and dispensaries. In this way a sum of more than one hundred thousand pounds annually might be contributed to these institutions by those who derive the greatest benefit from their existence." Let us hope that the effect of this appeal will be to elicit the sympathy of the working classes, and thus relieve the great responsibilities of those who administer hospitals and dispensaries.

THE WESTMINSTER UNION.

AT the meeting of the Board of Guardians of the Westminster Union, held at the board-room on the 15th inst., a copy of a letter which had been sent to Mr. J. D. Bliss, the master of the Poland-street workhouse, by the Local Government Board, was read. In this letter the Central Board, after reviewing all the facts connected with the official inquiry, the election of a new board, their suspension of Mr. Bliss, &c., conclude as follows:—"The Board cannot hold that the facts which were elicited at the inquiry, apart from any circumstances which have occurred since, do not justify the conclusion at which the guardians have arrived; and as the Board under the circumstances are not prepared to remove your suspension, they must request that you will at once place your resignation in the hands of the guardians." In accordance with this decision Mr. J. D. Bliss tendered the resignation of his office.

SANITARY INSPECTION OF PORTS.

DR. DE CHAUMONT, F.R.S., is engaged on behalf of the Local Government Board in inspecting the sanitary arrangements of many of our ports, in connexion with the state of preparedness to cope with cholera, should it be imported. At Faversham he found that in the absence of any infectious hospital a large barge would be held in readiness for the purposes of isolation. His inquiries both there and elsewhere included all relating to the inspection and disinfection of ships, the burial of bodies, and the landing of patients. He is reported as being favourable to cremation, could this system for the disposal of the dead be carried out in this country.

DRS. H. J. BIGELOW and R. M. HODGES have withdrawn their resignations from the staff of the Massachusetts General Hospital.

THE *Warsaw Courier* is reported to have published a letter from a subscriber, in which the writer offers himself as a subject to be experimented upon in reference to cholera. "I am unmarried," says he; "I have no ties of any kind, and no plans for the future. I therefore wish to be of use to humanity by undergoing any experiments which have not yet been tried upon human beings. I seek no reward, but should require to be paid my travelling expenses to wherever I might have to go to be experimented upon, and those of my return journey to Warsaw, should I be spared to perform it. I may add that I am twenty-four years of age, and in good health." The writer says that communications in answer to this may be sent to "Z. A. K., care of K. Tsibulski, china and glass dealer, Theatre-place, Warsaw."

AT a recent meeting of the Hampstead vestry, a deputation, representing a recently held public meeting of ratepayers, presented a memorial to the vestry, asking that body to move for an injunction to restrain the Metropolitan Asylums Board from continuing to use their North-Western or Hampstead Hospital for the reception of small-pox cases. The memorial was referred to the Sanitary Committee for consideration and report, and the vestry clerk was instructed to forward a copy of the same to the Metropolitan Asylums Board.

IN their report on the composition and quality of daily samples of the water supplied to London for the month ending July 31st, Messrs. Crookes, Odling, and Tidy state that, altogether, the quality of the water, as indicated by its state of aeration, and by its freedom from turbidity and excess of colour and organic matter, continued excellent.

THE members of the Queen's Colleges (Ireland) Commission have now closed their inquiry so far as regards the taking of evidence, and will examine no further witnesses.

DR. GEO. H. B. MACLEOD, Regius Professor of Surgery, University of Glasgow, has been elected Foreign Correspondent to the Academy of Medicine at Paris.

MR. J. HARRISON, M.R.C.S., has been elected Coroner for East Essex.

THE BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.

No. II.

BACTERIA ASSOCIATED WITH DISEASE IN MAN.

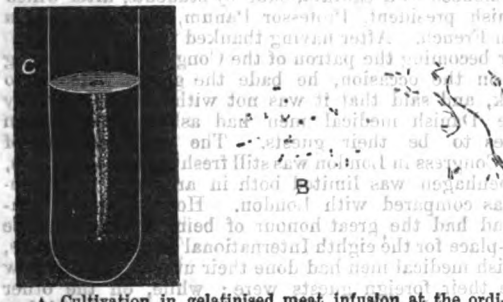
MICROCOCCUS OF PNEUMONIA.

THIS organism is found abundantly in the fluid expressed from the lung in cases of acute lobar pneumonia. It is a round or oval micrococcus (Fig. 5, A), which is surrounded

FIG. 5.

A, Fluid from the lung. B, Cultivation in gelatinised meat infusion. Objective $\frac{1}{12}$ in. The micrococci have lost their hyaline envelope. C, Test-tube cultivation.

by a hyaline envelope. It may be cultivated in gelatinised meat infusion, but the envelope disappears from the micro-



Digitized by Google

coccus under these conditions. (Fig. 5, B.) In test-tube cultivations (Fig. 5, C) it forms a characteristic figure, the so-called "nail cultivation." This consists of a large cushion-like expansion, at the point of which the needle enters the cultivating medium, and a rather slender growth along the needle track. The growth is of an opaque white colour. When a few minims of the cultivation are mixed with boiled distilled water and injected into the lungs or pleural cavity of a mouse, the characteristic appearances of acute lobar pneumonia are produced. After such an inoculation the organism is found to have regained the hyaline investment. If the cultivation is mixed with boiled distilled water, and a spray of this liquid is directed into a cage containing mice, a certain proportion of them are affected with acute lobar pneumonia. Injection and inhalation experiments with rabbits are not attended with any such results.

Bacillus of Typhoid Fever.

This bacillus is constantly present in sections of the ulcerated portions of the wall of the intestine of patients dying in the acute stage of the disease. It is also present in the mesenteric glands, and frequently in the liver, spleen, and kidneys, forming plugs in the small capillaries. It is short (Fig. 6, B), measuring about one-third the diameter of a human red blood-corpuscle. The breadth is one-third the length. When cultivated in gelatinised meat infusions, the appearance of the bacillus is somewhat altered. (Fig. 6, A.) It is larger, and tends to grow out into long filaments, in which

Fig. 6.

A, Cultivation in gelatinised meat infusion at the ordinary temperature. B, Cultivation in solidified blood-serum at the body temperature. Objective $\frac{1}{12}$ in. C, Test-tube cultivation.

by careful staining the individual bacilli may be distinguished. When cultivated in solidified blood serum at the temperature of the body (Fig. 6, B), the shorter form, similar to that observed in sections of the intestinal wall, is reproduced. The constant presence of this organism in the intestinal ulcers has led to the view that typhoid fever is the result of its agency. This has not hitherto been confirmed by the experiment of reproducing the disease by inoculation in other animals, as no other animal has been found which is subject to this disease. In this respect cultivations of the bacillus correspond with typhoid material direct from the body, as this, too, is inert when introduced into other animals.

Micrococcus of Acute Osteomyelitis.

This organism is constantly found in the pus of the abscesses in connexion with the bone, when they are opened. It is a small round micrococcus, which frequently occurs in pairs (Fig. 7, A). It may be cultivated in the usual manner, and causes the gelatine in which it grows to become liquid.

Fig. 7.

A, Micrococci from cultivation in gelatine. Objective $\frac{1}{12}$ in. C, Test-tube cultivation.

(Fig. 7, C.) The micrococci sink to the bottom of the liquid as a moderately compact orange-yellow precipitate. They also grow readily on potatoes,[1] forming orange-yellow colonies. When inoculated or introduced subcutaneously into a healthy rabbit, no pathogenic effect is produced. If, however, the bones have previously been injured, the injection of a quantity of the cultivation into the veins is followed by appearances resembling very closely those of acute osteomyelitis in man.

The Bacillus of Tubercle.

This bacillus is found in all tubercular affections (acute tuberculosis, phthisis, scrofulous diseases of joints, bones, glands, &c.), as well as in the sputa of phthisical patients, and in tuberculosis of the lower animals. It is a slender rod-shaped organism, measuring 2 to 4, rarely 8, μ in length. It often occurs in groups, and is frequently curved. In some cases it bears spores. In sections of tubercles the bacilli are found chiefly in the spreading region among the epithelioid and giant cells. They disappear as the part becomes cheesy. It may be cultivated at the body temperature on the surface by blood serum which has been sterilised and coagulated by heat. It forms irregular dry white scales and patches, which grow slowly. (Fig. 8, C.) Small portions of such

Fig. 8.

A, Bacilli from a tubercle. B, Portion of sputum of phthisical patient. Objective $\frac{1}{12}$ in. C, Cultivation in solidified blood-serum.

cultivations introduced into the subcutaneous tissues, the cavities of the body, or the blood of rabbits and guinea-pigs, cause the death of the animal from acute tuberculosis. This result may also be obtained by causing the animal to inhale a spray of phthisical material or cultivations, or by causing it to swallow the bacilli with its food.

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

Never has more splendid hospitality been offered to any body of men than that tendered by the city of Copenhagen and the whole Danish nation to the International Medical Congress, which concluded its labours on Saturday last. Never has the medical profession received a more heartfelt and noble recognition of the services which it renders, and tries to render, to humanity at large. Those who visited the Congress were one and all made to feel the warmth of their reception from the moment of landing on Danish soil. The formalities of the Custom-house at Korsor were dispensed with, and members of the Congress were at once bowed to their carriages, and on the arrival of the train at Copenhagen the members of the Reception Committee were at hand to give every assistance possible to the strangers. It has been stated that at the London Congress the choice of Copenhagen was made because it was felt that a city so inferior in size would certainly not attempt to outdo the hospitality of London. We cannot for a moment think that any vulgar notions of rivalry have actuated the Danes, but

[1] A potato cultivation is prepared as follows:—An old potato is taken and well scrubbed with a nail brush, care being taken not to injure the epidermis. It is then soaked for half an hour in corrosive sublimate solution (1-1000). It is then steamed for half an hour. While still hot it is cut in two with a hot knife, and the halves laid out in a dish protected from dust. When the potato is cool it may be inoculated with an organism, by means of the platinum needle, in the usual way.

we must in all fairness admit that no city in the world could have shown more lavish hospitality and more courtecus consideration for its guests than has the fair city of Copenhagen. We English are apt to think that domestic hospitality is the peculiar characteristic of our race, but we now know that this peculiar characteristic must assuredly have been inherited from our Danish ancestors. In Copenhagen, during the week of the Congress, the flow of private hospitality was continuous and splendid. Large dinner parties were given night after night to the more distinguished guests, and houses, servants, carriages, and horses were unreservedly placed at the disposal of the chiefs of medical science.

Of public hospitality there was an equal abundance. The municipality provided luncheon every day for the members, and in addition to this there were three splendid entertainments. On Wednesday there was an excursion to Elsinore, some 1500 persons travelling to that pleasant town by water, where, on their arrival, a luncheon was served in the Castle of Kronborg, which, strangely enough, has been taken by Shakespeare for the scene of the greatest of his plays. The building is romantic enough to give point to any passage even in such a play as *Hamlet*, but why the poet selected this particular castle as the scene of his metaphysical tragedy will ever remain a puzzle for human ingenuity to solve. From Elsinore the party returned to Copenhagen by special trains, many of the guests stopping to see the Castle of Fredericksborg, which was originally built by Inigo Jones for Christian IV. Inigo Jones's building was gutted by fire in 1859, but has since been restored with dazzling splendour by the munificence of a private citizen. On Thursday the municipality gave a splendid dinner to 1200 guests in a wooden building specially erected on the quay at Copenhagen. This dinner was most successful. Notwithstanding the number, it was well served, and the glee-singing by the students and the musical performances by the band will not readily be forgotten by those who were present. The room was necessarily too large for effective speaking, but those who were within earshot could not but enjoy the simple and effective oratory of the Governor of Copenhagen, of M. de Bille, of Pasteur, Virchow, and Paget. After dinner the whole company embarked on four steamboats, and made a triumphal progress to the Tivoli Gardens. The whole of the shipping was gaily festooned; the boat-clubs rowed past the steamers and tossed their oars in honour of the guests; coloured lights were displayed, bands played, and the quays were packed with a dense crowd of spectators, cheering and waving hats and handkerchiefs. At the Tivoli Gardens were some 25,000 persons in addition to the members of Congress, and here ample amusement was afforded in the shape of music, illuminations, fireworks, and a variety of theatrical and other performances. The night was mild and lovely, and it was past midnight before the company finally separated. On Friday, the last day of the Congress, the most splendid of all the entertainments was given by the King at the Christiansborg Palace. The guests assembled at 8.30, and soon the vast and noble rooms were crowded almost to excess. At 9.30 the Royal party arrived, including the King and Queen, the King and Queen of Greece, the Crown Prince and Crown Princess, Prince Waldemar, Princes William and John of Glucksbourg (brothers of the King), and the ladies and gentlemen of the Court. The leading members of the Congress were presented to their Majesties by the ambassadors from their respective countries; and among those who received this honour through the mediation of the Hon. Mr. Vivian, the British ambassador, were Sir James Paget, Sir W. Gull, Sir S. Wells, Sir Risdon Bennett, Sir W. Mac Cormac, Sir H. Acland, Professors Priestley, Ogston, Marshall, Macewen, Chiene, Stokes, Watson, Poore, Knowsley Thornton, and others. This ceremony concluded, their Majesties walked through the crowded rooms to the supper-room, a noble hall, where a truly regal repast was provided, during which the King's musicians discoursed most excellent music. The supper ended, the King proposed, in a few kindly, dignified words, the health of his guests, and expressed the honour which he and his subjects had felt in receiving the Congress. Sir William Gull, at the request of Professor Panum, the President, thanked their Majesties on behalf of the Congress, and said that never had the profession of medicine been more honoured or so royally entertained. Sir Wm. Gull's speech was short, courteous, and judicious, and was received with every mark of satisfaction by his medical colleagues. No Englishman who was present at this Royal *fête*, and who experienced the kindly courtesy of the King and Queen of Denmark and the Danish Royal Family, could fail to see whence was derived the beauty, dignity, and kindliness which have given to the Princess of Wales her undying popularity, and have made her at once respected and beloved by the whole English people. The British members of the Congress cannot but feel grateful to the Hon. Mr. Vivian for the hospitality and courtesy which were shown by his Excellency to all subjects of the British Crown who visited the brilliant Congress of Copenhagen.

(*From our own Correspondent.*)

The eighth International Medical Congress was opened on Sunday, August 10th, in Copenhagen, by a festival which was attended by more than 1500 people. Until a few days before the opening of the Congress only about 500 foreign medical men had registered their names, but on Friday, Saturday, and Sunday an equal number arrived. As all the hotels had been taken long ago by those who had applied to the Reception Committee for rooms, all the new comers were either received as guests in Danish families or went to private boarding-houses. On Monday night, the number of members of the Congress present amounted to more than 1700, of which about 500 were Danish. The festival, which was honoured by the presence of the King of Denmark, who is the patron of the Congress, and by the Royal Family, amongst whom were seen the King and Queen of Greece, was commenced by a cantata, sung by students, after which the Danish president, Professor Panum, rose and made a speech in French. After having thanked the King of Denmark for becoming the patron of the Congress and for being present on the occasion, he bade the guests welcome to Denmark, and said that it was not without some anxiety that the Danish medical men had asked their foreign colleagues to be their guests. The great success of the last Congress in London was still fresh in their memories, and Copenhagen was limited both in area and accommodation, as compared with London. However, as Copenhagen had had the great honour of being selected as the meeting-place for the eighth International Medical Congress, the Danish medical men had done their utmost to show how welcome their foreign guests were; while, on the other hand, they reckoned very much upon their guests' forbearance. Professor Panum then thanked the Committee for the last Congress in London, for those never-to-be-forgotten days, and he was happy to be able to personally thank Sir James Paget and Sir Wm. Mac Cormac, who were then present. He then said that national prejudices ought to have no place at an International Congress such as this; the different languages, instead of being as flags to point out the speaker's nationality, should be as sails which enabled men of different nations to approach each other. The famous Tower of Babel differed from modern science, because the latter came from heaven and demanded sacrifice and humility on the part of those who worked in its service; while vanity, selfishness, and jealousy between nations would only produce a weak building, which would soon go to pieces. Sir James Paget then rose, amid loud cheers, and spoke in honour of the Danish Royal Family, to which England especially was much indebted, because it had given England the Princess of Wales, who was a model to her sex as wife, mother, and Princess. Sir James Paget's speech, the language of which was elegant and the style perfect, was received with loud applause. Virchow then spoke about the development of medical science, in which Scandinavians had lately taken so great a part. He, too, laid stress upon the international character of the Congress. Science was only one and the same everywhere. M. Pasteur, who was received with loud cheers, expressed his thanks for the hearty welcome which the foreigners had received. Like the former speakers, he laid stress upon the neutrality of science, which, however, in no way prevented every great scientific man from being a great patriot and from adding to his country's honour. After the general secretary, Lange, had made a report of the preparations for the Congress, and M. Panum had given the history of the International Medical Congresses, the following vice-presidents were elected:—For England: Sir J. Paget, Sir W. Gull, Sir William Mac Cormac, Sir Henry Acland, Sir Risdon Bennet, Sir S. Wells, Profs. Erichsen, Watson, and Marshall. For America: Billings and Austin Flint. For Scandinavia: A. Key, Dahl, and Hjelt. For France:

Digitized by Google

Pasteur, Verneuil, Chauveau, Ollier, Jaccond, Hardy, Ranvier, Cornil, Trélat, Lépine, and Bouchard For Germany: Virchow, Kölliker, His, Frerichs, Volkmann, Esmarch, Hensen, Flemming, Henoch, Münk, Liebreich, Liebermeister, and Gurlt. For Austria: Schnitzler. For Holland: Tilanus, Rosenstein, and Engelmann. For Russia: Reyer and Rauchfuss. For Italy: Crudeli and Bottini. For Belgium: Crocq. For Switzerland: Lombard, Prévost, Meyer, and Kollmann. As secretaries were elected—Kronecker, Petit, Owen, Poore. In the evening the President gave a dinner to about 300 members of the Congress. After dinner Sir James Paget spoke for Denmark, Virchow for Copenhagen, Pasteur for the Danish hospitality, and Crocq for Professor Panum.

On Monday, the 11th, the different sections were formed. It was decided that the list of the Danish presidents should stand, with the exception of the section of Laryngology, whose Danish president, Dr. Wilhelm Meyer, was a president also for the Otological section; in his stead Dr. Morell Mackenzie was elected president

The most prominent paper read on Monday was that of Professor Pasteur on Pathogenic and Vaccinia Microbes, which altogether seems to have been the one to which most interest was attached during the Congress. Pasteur's speech was principally a report of the work done in his laboratory during the last four years. His own and his pupils' labour has been entirely devoted to the question of hydrophobia inoculation, and his experiments have been both numerous and thorough. As the results of some of these have already been published, only a brief summary of the first part of the speech can be given. He first called attention to the fact that the characteristic changes of the tissues in animals which had died from hydrophobia are often limited to the medulla oblongata, in which organ the poison producing the disease is found most concentrated and pure. Secondly, to the fact that inoculation of the poison obtained from the medulla oblongata is not always followed by positive results, unless the poison is introduced into the subarachnoid cavity by means of a trocar, after trepanning the skull has been performed. These two facts have been of vast importance in solving the great difficulty in obtaining the poison sufficiently concentrated for experimental purposes, experience having shown that two dogs, both bitten by the same rabid dog, may take the disease in quite different degrees and after longer or shorter periods of incubation. Liability to error may, however, be obviated by pursuing the following method:—Take the medulla oblongata from a dog which has died of rabies, crush and put it into sterilised bouillon, taking all necessary precautions. By introducing two drops of this preparation into the subarachnoid cavity of rabbits by means of a Pravaz syringe, the same results will always be produced; the rabbits will all develop hydrophobia within twelve to fifteen days, neither more nor less. It is, however, necessary to take the poison from dogs whilst the disease is at its maximum, otherwise the period of incubation will be very different. By transferring the poison, originally taken from a dog from one rabbit to another, from a second to a third, and so on, Pasteur has come to the result that after the tenth inoculation the incubation period is reduced to from eight to nine days. After this point the incubation period is of exactly the same length until the fifteenth inoculation, which during the last few days he has succeeded in reaching. Guinea-pigs reached the incubation period proper to them after a shorter series of inoculations, but neither in these animals nor in rabbits or dogs is it possible to weaken the poison by inoculation. Pasteur has, however, succeeded in finding animals in which it is possible. The latter part of the speech was as follows:—"Jenner first propounded the idea that the poison which he called 'grease,' but which we now more accurately call horse-pox, must, before it can be given to man without danger, be weakened in its poisonous effect, if I may use the term, by being transferred to the cow. After this the idea of weakening the hydrophobia poison by introducing it into certain animals seemed worthy of a trial. Many experiments were made, but in the greater number of animals experimented upon the poison only increased in virulence, as, for instance, in rabbits and guinea-pigs; happily monkeys proved an exception. On the 16th December, 1883, a monkey was inoculated by trepanning from the medulla oblongata of a dog, whose rabid state had been confirmed by the fact that it had bitten a child who afterwards died of hydrophobia. The monkey became mad eleven days after. From this one the poison was given to a second monkey, which also became mad in the course of eleven days. A third monkey was only attacked after twenty-three days. From the medulla oblongata of each monkey two rabbits were inoculated. The rabbits inoculated from the first monkey were seized after thirteen and sixteen days, those from the second monkey after fourteen and twenty days, those from the third after twenty-six and thirty, those from the fourth after twenty-eight, from the fifth after twenty-seven, and from the sixth after thirty days. It cannot be doubted after this that by transferring the poison from monkey to monkey and from several monkeys to rabbits, it at last became weakened. In the same way it is weakened in dogs. A dog which was inoculated from the fifth monkey had an incubation period of fifty-eight days, although the inoculation was done by trepanning. Other experiments of the same nature led to like results. Thus, we are now in possession of a method by which the contagious power of hydrophobia is weakened. Inoculations from monkey to monkey produce a poison which, when given to rabbits, has an incubation period which gradually increases in length. If, on the other hand, the poison is given to a succession of rabbits it becomes subject to the law already mentioned, by which it increases in violence when transferred from one rabbit to another. From the application of these facts we obtain a means of inoculating dogs against hydrophobia. As a starting-point is taken a rabbit poisoned from a monkey, which has been inoculated by poison that has gone through so many individuals that it is not able to cause death through hypodermic or intravenous injection. Having now applied this method for protecting dogs against hydrophobia, and having collected a large number of dogs which had been made impervious to infection, I determined, as I had a higher aim in view, and remembering the opposition which Jenner had encountered, to place the results, which, in my opinion, are the ground-plan of the protection of dogs against hydrophobia, before a competent commission. The Minister of Education, M. Tallières, to whom I spoke on the subject, was willing to support me, and he appointed MM. Béclard, P. Best, Bouley, Tisserand, Villemin, and Vulpian to examine the facts which I had already laid before the Academy of Sciences at its meeting of the 19th of May last. The Commission, having chosen M. Bouley as president and M. Villemin as secretary, at once set to work, and I have the pleasure to announce that it has within the last few days sent its first report to the Minister. The Hydrophobia Commission has up to the present experimented on thirty-eight dogs, of which nineteen were from me, and declared to be impervious to contagion, whilst nineteen were unvaccinated. Those dogs which have not died under treatment are still under observation, and will be for some time to come. As far as the condition of those dogs which have been experimented upon is concerned, of the nineteen unvaccinated, three out of six of those bitten have become mad, five out of seven of those inoculated in the popliteal vein have become mad, and all of the five which were inoculated by trepanning have become mad, whilst not one case of hydrophobia has declared itself amongst the nineteen vaccinated dogs. One vaccinated dog died on July 13th from hæmorrhagic diarrhœa, which had shown itself in the first days of July. In order to see whether hydrophobia had had any part in its death, three rabbits and one guinea-pig were at once inoculated by trepanning from its medulla. These four animals are still in perfect health, which is a certain proof that the dog did not die of hydrophobia, but of an ordinary disease. The next report from the Commissioners will treat of the history of twenty dogs, the inoculation of which they will superintend themselves."

Pasteur's speech was received with enthusiastic applause from the numerous audience who had followed with great interest the reading of the paper.

I must defer the conclusion of this report until next week.

STRAY NOTES ON THE CONGRESS.

(By an Occasional Correspondent.)

The President's dinner at the Hôtel d'Angleterre, on the first Sunday evening of the Congress opening, was a very brilliant affair. The guests must have numbered at least two hundred and fifty, and the *menu* of viands, wines, and music could not be excelled for exquisite selection. In form the *menu* is a masterpiece of elegant humoristic art. The guests were soon made acquainted with a Danish peculiarity not very favourable to the digestion of an excel-

Digitized by Google

lent dinner. Our Scandinavian friends begin the toast list soon after the repast has well begun, and the President rose to do honour to the King of Denmark just when the guests were discussing the relative merits of roast beef à l'Italienne and poulets sautés à la Marengo. When presently Sir James Paget was called upon to propose "Prosperity to Denmark," he playfully referred to the custom of toasting and cheering during dinner, and suggested that, with all deference to the hosts, this was one of those customs almost "more honoured in the breach than in the observance." By common consent Sir James's speech was perfect in matter, form, and delivery, and it rose to eloquence and pathos as he concluded by asking permission to convert the toast into a prayer, "May God preserve Denmark," a sentiment which was responded to with unbounded enthusiasm, all the more telling in that a very large proportion of the guests were Prince Bismarck's countrymen. The dinner over, the sight was a brilliant one, as the crowd of guests descended into the spacious courtyard of the hôtel, covered with glass, lighted by electricity, and decorated with exotic plants. Over Chartreuse and coffee the question was soon mooted amongst various groups of talkers, Where shall the next Congress be?

At the opening ceremony in the morning a fertile theme with speakers had been the superiority of science over distinctions of creed, rank, and nationality. But once more abstractions did not stand the test of serious practical difficulty. When Berlin was mooted for 1887, it soon became seriously questioned whether the international character of the Congress could be maintained in the absence of the representatives of one of the leading European nations. The Parisian crowd once shouted "à Berlin," but were the academicians likely to echo the cry? The mere doubt was almost fatal to the project, and the distinguished American representatives, Dr. Austin Flint and Dr. Billings, saw and made the best of their opportunity. So it has come to be decreed that the next cosmopolitan gathering of doctors is to be on the other side of the "herring pond."

On Monday the sections gathered for work, and as I entered the surgical one, allowing for different sizes of rooms, the attendance at Copenhagen seemed decidedly more numerous than it was when Mr. Erichsen first took the chair at Burlington House three years ago. Professor Panum presided at first, and after referring to the recent and deeply regretted death of Professor Holmer, who had taken a most active part in organising the Congress, Sir Henry Acland, as one who had known him personally, was called upon to express the condolence of his colleagues. This he did in a brief but most apt speech. As he delivered it, I was forcibly struck with the resemblance of Sir Henry as he now is with Professor Sharpey as he looked about twenty-five years ago. The Oxford professor is not quite so massive in build as the veteran physiologist, but the resemblance is most striking. Professor George Buchanan of Glasgow was independently much struck with it, and observed to a mutual friend that he thought it was Sharpey come to life again when he saw Sir Henry at the presidential dinner the previous evening.

Professor Panum now vacated the chair in favour of Professor Volkmann, and the section was in eager expectation for Sir Joseph Lister's promised address on the Listerian Antiseptic Treatment in its present form. But as the baronet was not present, Professor Esmarch made a short speech on Malignant Diseases of the Rectum, which was illustrated by schematic diagrams. The *pièce de résistance*, and a very rich and substantial one it proved, was Mr. Thomas Bryant's communication on Lumbar Colotomy as a Curative and Remedial Operation in Syphilitic, Simple, and Cancerous Ulceration of the Rectum and Colon, with an improved method of performing the operation. A very full and well-arranged abstract of Mr. Bryant's paper was in the hands of members, who were thus enabled to follow him through the analysis of his eighty-two cases of colotomy, an unrivalled experience for any one surgeon. Forty per cent. of the whole number of eighty-two cases operated upon died within the month. Of the forty-nine successful cases, sixteen died within six months, eight lived from six to twelve months, twelve from one to five and a half years, five were alive from one and a half to fourteen years after operation, while eight had left the hospital convalescent. The manner of the delivery of the address was worthy of the matter, and, all in all, British surgery could not have had a better representative. Professor Verneuil followed on Inguinal Colotomy, and Professor Trélat on the Lumbar Operation, substantially endorsing Mr. Bryant's teaching and practice. The President then called upon Mr. Sampson Gamgee of Birmingham, who, in compliance with a generally-expressed wish, addressed the section in French. He avowed that, since he had had the personal instruction of Amussat, he had always practised his peration; but his recent observations in Professor Verneuil's clinique, and the experience of his colleagues, Mr. Furneaux Jordan, Mr. Bennett May, and Mr. Jordan Lloyd, in the Queen's Hospital, Birmingham, had convinced him that in well-chosen cases inguinal colotomy was an easy, safe, and efficient operation. The prevailing feeling of the section was a hopeful one as to the possibility of affording great relief in malignant rectal disease by timely and suitable surgical intervention.

If these Congresses are supposed to be holidays, they certainly are very hard-working ones to some of us. What with heat and dust and talk, repose is neither easy nor frequent; and as I am very anxious for a run home through the cliniques of Halle, Berlin, and Vienna, I shall not for the present inflict on THE LANCET readers any more stray notes from the Copenhagen Congress.

HEALTH OF THE ARMY.

No. I.

THE annual report on the health of the army during 1882, which has just been presented to Parliament, shows the strength of the white troops serving at home and abroad to have been 174,557. The admissions into hospital during the year were in the ratio of 1093 per 1000, the deaths 12·06, the discharges by invaliding 19·45, and the constantly non-effective from sickness 54·21 per 1000. With the exception of the invaliding, which shows a slight increase, these ratios were all under those of the preceding year, but the admissions and constantly sick were above the average of the last ten years.

Among the troops serving in the United Kingdom the admissions amounted to 852, the deaths to 6·94, the discharges by invaliding to 24·55, and the mean daily sick to 47·12 per 1000, in a strength of 86,847 non-commissioned officers and men. These are all lower than in the preceding year except the proportion invalided, which shows an increase of 2·36 per 1000, a result probably of the Egyptian campaign. The reduction does not appear to have been confined to any particular class of diseases. The admissions and deaths from enteric fever amounted to 2·0 and ·47 per 1000 of the strength, being more than double the proportion which occurred in 1881. The increase is stated to have been principally due to its occurrence among men recently returned from active service in Egypt. This was especially the case in the Home District and at Aldershot. In Dublin, where 27 cases and 5 deaths occurred, several of the cases "originated in the Royal Barracks, which are reported to have been badly constructed originally, too close to the river Liffey, and to have faulty drainage; various sanitary improvements have since been undertaken." Scarlet fever prevailed in a severe form at the Curragh from May to October, causing 35 admissions and 3 deaths; it was also prevalent at Chatham, where there were 23 cases with 1 death. Erysipelas was the cause of 269 cases, with 4 deaths; the largest number occurred at Aldershot, where the principal medical officer was unable to trace them to any insanitary condition either of the quarters or the neighbourhood. The Dublin and Cork districts furnished the next highest proportion of cases, and 3 out of 4 deaths occurred at the Curragh. Comparing the different military districts with each other, the Dublin district is found to furnish the highest ratio of admission, and the southern district the highest of deaths and constantly sick. This result, as regards the latter, is probably to a great extent due to the number of regiments returning from foreign service which arrive at Portsmouth, bringing with them cases of chronic disease, often in an advanced stage.

The returns by arms of the service show the admissions to have ranged between 573 per 1000 in the Royal Engineers and 956 in the Foot Guards; the deaths between 6·32 in the Household Cavalry, and 9·69 in the regimental depôts; and the mean sick between 29·78 in the Royal Engineers and 51·82 in the Foot Guards. Although the Royal Engineers had the lowest rates of admissions and daily sick, they fur-

Digitized by Google

nished the highest ratio of deaths, except the depôts, amounting to 8·16 per 1000, the Foot Guards coming next with a ratio of 8·14 per 1000. We regret to observe the omission from the present report of the table hitherto given of the deaths to the end of the year among invalids discharged to pension from the different arms, as they ought to be added to furnish a fair statement of the death-rate of our troops at home. No reason has been assigned for the omission. The sickness and mortality among the officers serving at home are stated at 311 and 4·64 per 1000. Among the women, the cases, exclusive of parturition, were 439 and the deaths 8·10 per 1000; and among the children the attacks of illness were in the ratio of 490 and the deaths 26·79 per 1000, nearly one-fourth of the cases being measles.

At Gibraltar, in an average force of 4558 men, the ratio of admissions into hospital was 817, of deaths 10·31, of invalids sent home 14·70, and of constantly sick 50·35 per 1000. These results do not differ materially from those of 1881, except as regards the deaths, which have been more than doubled; all the ratios however, except the invalids sent home, are considerably above the average of the last ten years. The excess of deaths was chiefly due to enteric fever, and, though to a less extent, to fatal injuries. In the returns 40 cases of enteric fever appeared, of which 18 proved fatal. The surgeon in charge of the station hospital attributed the prevalence of enteric fever to deficient rainfall, but Surgeon-General Smith states that the troops were well supplied with good water, and believes it to have been mainly due to the fact that, owing to the change of troops in connexion with the Egyptian campaign, the garrison was almost entirely composed of unacclimatised soldiers just arrived from England. "The younger men on first arrival suffered much from fever, which in many instances assumed the enteric form, with the high rate of mortality of that disease."

The strength of the troops in Malta, exclusive of the Royal Malta Fencible Artillery, was 4619. The admissions into hospital were in the ratio of 804, the deaths of 8·88, the invalids sent to England of 36·37, and the mean daily sick of 52·35. With the exception of the invaliding, these results compare very favourably with those of the preceding year, and the admissions and deaths are both under the average of the last ten years. The reduction in the admissions has been chiefly in fevers, and in the deaths in fevers and tubercular diseases. The reduction in the amount of fevers would probably have been still more marked but for the arrival of four regiments from England, three of them at the hottest period of the year, to relieve corps which were ordered to proceed for service in Egypt. The influence of this circumstance upon the sickness and mortality in the command may be estimated by the fact that the *annual* ratio of admissions and deaths in five line regiments which were in the island at the beginning of the year was 645 and 5·87, while in the four regiments which arrived from England during the year it was 1229 and 12·58 per 1000. Enteric fever furnished 78 cases and 13 deaths, being in the ratio of 16·9 and 2·81 per 1000 of the strength, October and November being the months in which it was most prevalent. It is stated that it was impossible "to trace the disease to any definite cause or to any insanitary condition of the barracks themselves."

The admissions and deaths in the Royal Malta Fencible Artillery amounted to 606 and 12·62, and the constantly sick to 22·81 per 1000 in an average strength of 317. The sickness was considerably under, but the deaths double, the average of the ten preceding years; but the numbers are too limited to justify any positive deductions. A new scale of rations was introduced into the corps during the year, and the change is favourably reported upon by the medical officers.

The average force at Cyprus during the year was 595; in September and October it consisted chiefly of the depôts of corps serving in Egypt; before and after these months it was composed of a wing of a line regiment and detachments of Royal Engineers and Departmental Corps. The ratio of admissions into hospital during the year was 1004, of deaths 11·76, and of constantly sick 46·89 per 1000; all in excess of the results for the previous year. The excess of sickness and mortality was probably due to the arrival of troops in the hottest and most unhealthy season of the year, and to the 1st Battalion Royal West Kent Regiment landing in the island from Egypt, after the termination of hostilities, "in a most sickly and debilitated condition." There were 21 cases and 3 deaths returned under the head of enteric fever, but in all except two cases the disease was believed to have been contracted in Egypt.

In the Dominion of Canada, the average strength of the force stationed at Halifax, N.S., was 1892, and consisted of Royal Artillery, Royal Engineers, two line regiments and detachments of the Departmental Corps. The admissions into hospital were 710, the deaths 3·70, the invalids sent home 11·10, and the constantly sick 32·88 per 1000 of strength, all lower than in the preceding year, and the deaths only half the average of the last ten years. No case of enteric fever occurred; the most prevalent diseases were tonsilitis, dyspepsia, and diarrhœa.

At Bermuda, in a force of 1446, the admissions into hospital were 661, the deaths 8·99, the invalids sent home 15·91, and the constantly sick 33·04 per 1000. Except the invaliding, these ratios are very slightly above the average of the last ten years. The excess in the admissions was chiefly due to venereal diseases. Dengue prevailed as an epidemic among the civil population, but affected the troops to a very slight extent. There were 21 cases and 2 deaths from enteric fever; 14 of the cases occurred at Prospect Island, but could not be traced to any local cause.

In the West Indies, the average strength of the white troops was 492 non-commissioned officers and men, among whom the cases amounted to 675, the deaths to 10·16, the invaliding to 10·16, and the mean sick to 37·28 per 1000, results much under the average of the last ten years. The reduction in the admissions and deaths was almost entirely in the class of fevers, which furnished only 45 and 2·03 per 1000 of the strength. There was no case of yellow fever, which prevailed so much at Barbadoes in 1881, and only one case of enteric fever at Newcastle, Jamaica. Among the black troops, averaging 1120, the ratio of admissions was 1029, of deaths 16·96, of invaliding 41·96, and of mean sick 59·47 per 1000—results which, although they differ but little from the average of previous years, contrast very unfavourably with those of the white troops. Tubercular diseases were the principal causes of the mortality, and next to them diseases of the digestive system. Syphilis and gonorrhœa were the most prevalent diseases, and together furnished more than one-fourth of all the cases.

On the West Coast of Africa, the admissions from a force of 580 black troops amounted to 1247, the deaths to 27·58, the invaliding to 1·72, and the mean sick to 60·84 per 1000; the ratio of deaths was slightly above, but the other ratios considerably under, the average. Tubercular diseases were the chief source of the very high rate of mortality, one-half of all the deaths having resulted from them. Gonorrhœa, paroxysmal fevers, and diseases of the digestive system were the principal causes of admission into hospital. The cause of the great mortality from phthisis among the black troops in the West Indies and West Africa is a subject deserving careful investigation.

The average strength of the force employed at the Cape of Good Hope and St. Helena was 3944. The admissions into hospital were in the ratio of 697, the deaths of 19·52, the invaliding to England of 33·72, and the mean sick of 56·83 per 1000. These, except the mean sick, are much below the average of the preceding ten years. The high ratio of mortality was due to enteric fever, for if it were omitted the death-rate for the year would only be 7·60 per 1000. There were 240 cases and 47 deaths returned under this head, all of which occurred in Natal. These numbers give the proportion of 61 cases and 11·92 deaths per 1000 of the whole force in the command; but if calculated on the strength of the troops in Natal alone, averaging 2701, the cases would be 88·8, and the deaths 17·40 per 1000. At the close of 1881 this disease was very prevalent among the troops in Natal, and continued so during the first quarter of 1882, when it abated, and only 8 cases and 4 deaths occurred in the second quarter. The principal medical officer attributed the disease to the impure water supply at the up-country stations in Natal, "where the water-supply was, in all, open to serious objections, but unavoidable in camp life." At Cape Town small-pox was epidemic among the civil population, but only two cases occurred among the soldiers, 1038 in number.

In the Island of Mauritius, the admissions into hospital from the average force of 892 amounted to 2476, the deaths to 13·08, the invaliding to 28·56, and the mean sick to 95·18 per 1000. This very high ratio of admissions, which is considerably above that of 1881, was chiefly the result of the continued prevalence of paroxysmal fevers, which amounted to 14·50 per 1000, though fortunately attended with a com-

Digitized by Google

paratively low rate of mortality. The disease seems to be generated at Port Louis, as the senior medical officer states "that there does not appear to have been a single admission from malarial fever at Curepipe unless the patient had suffered from the disease previous to his being sent there." Unfortunately, he does not tell us what proportion of the force is quartered at each of these stations respectively. Surely some steps might be taken, and certainly ought to be taken, to find a more healthy spot in which to quarter the troops, when in their present barracks one-tenth of the force is constantly in hospital, and the cases of fever alone are in the proportion of three attacks to every two men. Any reasonable expenditure should be incurred to save our soldiers from such unnecessary deterioration of health and efficiency. Is there any imperative necessity for keeping the troops quartered at Port Louis?

HOME HEALTH RESORTS.

No. II.

THE picturesque village of Shelfanger, near Diss, in Norfolk, has recently assumed a position of some prominence, owing to the discovery of a valuable spring of natural mineral water. The water is said to be most palatable, and has been analysed by Professor Attfield; the chief ingredients are carbonates of iron and magnesia. A capital residence for the reception of visitors has been fitted up, and the grounds have been made as attractive as possible. Two of the principal features of the place are the artistic drinking-fountain and the covered swimming-bath. An observatory has also been erected on the premises, from which fine views of the surrounding country may be obtained.

Ilkley, which was formerly known as the Mountain Spa, is situate on the southern slope of the beautiful Wharfe valley, with the extensive range of Rumbold Moor in the near distance. The walks in the immediate neighbourhood are plentiful and picturesque, and the scenery within a few miles of the spa is said to be amongst the finest in England. The hydropathic establishments are numerous and well appointed, and that known as "The Spa" has good chalybeate springs. There are several good hotels, and private lodgings can be had. The site is about 700 feet above the level of the sea. The cold waters are derived from rocky streams, which are for the most part at about a temperature of 47° F. Bathing and drinking are both practised at this resort. Scrofula, diseases of deficient vitality, stiff joints and muscular contractions, and gastric irritability, are the chief diseases which have been benefited. Ben Rhydding is situate in this elevated and bracing region of Yorkshire. Malvern, Matlock, and Sudbrook-park, are all celebrated for their cold-water cures.

Clifton has its particular advantages of temperature, air, and locality, which, in the hands of a judicious practitioner, might be made available in many cases where probably no other situation or measure would avail. Fifty years ago the mianamed Hot Wells of Clifton were more spoken of than they are now. The temperature of the springs is about 73° F. Though not insipid, the taste of the waters is hardly so pleasant as those of Malvern or Ilkley. The chemical constituents are few and simple; the whole amount of them in a pint of water is about eight grains, sulphate of soda being one of the principal ingredients. Clifton is built in terraces on the southern declivity of a hill of carboniferous limestone and hard sandstone. The soil rapidly becomes dry, and the air appears to be less humid than on the South Devon and Cornwall coasts, and the fall of rain seems to be less. The winter temperature is about three degrees cooler than at Torquay. The houses in the neighbourhood of the Bristol Hot Wells, near the bottom of the hill, are the most sheltered. There is good ground for exercise, and the surrounding country is attractive

Woodhall ought to be a very important English spa; it is situated between Boston and Lincoln. According to Mr. Cuffe's pamphlet on this spa, a gallon of water contains 1215 grains of chloride of sodium, 105 of chloride of calcium, 86 of chloride of magnesium, rather more than 5 grains of bromide of sodium, and more than 2·5 grains of iodide of sodium. Although this resort has got the name of the "Iodine Spa," it is probable that the iodine plays only a secondary part in its therapeutic action, as is the case with the "Haller Jod-Wasser," or of the "Adelheidsquelle." Braun is therefore inclined to ascribe the good effects of the Woodhall waters to the chlorides and other conditions, rather than to the iodide and bromide.

The Beulah Spa, near Norwood, appears to be once again rising in public estimation; the waters contain 61 parts of sulphate of magnesia and 9 of sulphate of soda, and belong, therefore, to the class of bitter springs, which are mostly prized for their purgative tendencies.

The Purton Spa, near Swindon Junction, ought to prove useful in many cases if methodically used under medical guidance and with a proper régime. It contains 23 grains of the sulphates of soda and magnesia, with 10 grains of sulphate of lime, 3·6 of carbonate of potash, and 4·2 of chloride of sodium, and is impregnated with 6 cubic inches of carbonic acid, in which most English and also most foreign bitter waters are defective. The mild aperient effect is, however, somewhat counteracted by the large proportion of gypsum.

Cheltenham waters may be classed both among the salt and bitter springs. No. 4 Montpellier contains 52 grains of chloride of sodium to the pint. The sulphates consist of 17·2 grains of sulphate of soda and 14·2 of sulphate of magnesia. The constitution of Pitville saline water is similar, though not identical. The principal defects of these waters are the small proportion of carbonate of soda and carbonic acid; but these might be remedied by the addition to every tumbler of a certain quantity of Bilin or Fachingen or Vals water, and the temperature might be regulated according to the individual cases. If this suggestion were carried out, and the local practitioners became thoroughly interested in the methods of administration, there seems to be no reason why Cheltenham and also Leamington should not again become much-frequented and useful watering-places, the more so as in many instances they could be resorted to also in early autumn and even winter, on account of the greater mildness of climate as compared with continental spas. Cheltenham also possesses a fairly strong chalybeate, with ·83 grain of ferrous carbonate, 6 grains of other salts, and an amount of carbonic acid sufficient for use at the well, though not for transmission. The summer temperature of Cheltenham is stated by Dr. Macpherson to be 2° cooler, and the winter temperature 3° warmer, than that of London.

Leamington may also as reasonably be classed with the mixed sulphated waters as with muriated. These cold springs contain no sulphate of magnesia, but only sulphate of soda, ranging from 28 to 40 grains per pint in different springs. The saline spring contains, in addition to 40 grains of sulphate of soda, 40 of common salt, 20 of chloride of calcium, and 3 of chloride of magnesium, with traces of iron, bromide, and iodine, and 2 cubic inches of carbonic acid. The saline chalybeate contains only 32 grains of sulphate of soda, with over 60 of chloride of sodium, 20 of chloride of calcium, and 12 of chloride of magnesium, about 1 grain of iron, and 3 cubic inches of carbonic acid. There are, besides, a sulphuretted saline and several other springs. The advantages of the springs for some cases are obvious, and the defects for others might be remedied by warming and the addition of other mineral waters.

Builth, in North Wales, may before long take a high place as a health resort; the saline waters are the principal ones, though there are also weak sulphur wells. We have been informed that barium chloride exists in appreciable quantities in some of the springs.

PROFESSOR MAX VON PETTENKOFER ON CHOLERA AFLOAT.

IN the scientific supplement to the *Allgemeine Zeitung* of Munich (August 13th, 1884), this well-known authority on bygiene takes up the question of the occurrence of cholera at sea. He restricts his investigation to the outbreak just thirty years ago on board H.M. flagship *Britannia* during the Crimean war, an outbreak on which a report was written by Dr. Milroy, but of which an eye witness has just enabled Professor von Pettenkofer to give a fuller and, in present circumstances, a more interesting account.

The *Britannia* was in the spring of 1852 fitted out as a

Digitized by Google

flagship; spent the first year chiefly at Malta; went in August, 1853, to Besika Bay; in October to Constantinople, where she remained the whole winter; and in March, 1854, after the declaration of war, to Varna. With the exception of a short run to Odessa and Sebastopol, she was there the whole summer. In August the cholera broke out, at first among the troops on shore. Till then the ship and the whole fleet were in perfect health. It was thought that the French had brought the cholera with them from the Dobrudscha, whither some regiments had been sent from Varna. Few of these returned, the majority having succumbed in the lower levels of the Danube to cholera, typhus, and malaria.

The cholera among the land troops having ceased, it broke out in the fleet, but in very unequal proportions. There were then lying off Varna fifty-four English, French, and Turkish vessels of the line, with a host of smaller craft. The *Britannia* lay on August 20th in Kavarna Bay, fifteen leagues from Varna. Some hundred yards from her lay two other English three-deckers, the *Trafalgar* and the *Queen*, each, like the *Britannia*, with a crew of 1040 men. The *Britannia* lost 139, the *Trafalgar* 6, and the *Queen* 4 from cholera. On the French and Turkish ships the case was similar. It is remarkable that the French flagship, equally with the English, was most violently attacked. It lost 162, among them three officers. Throughout the malady the French flagship (*Ville de Paris*) remained at anchor in the roads with the rest of the fleet. The *Britannia* put out to sea in hope of bettering herself. How this was disappointed we know. While, then, the cholera on board the *Britannia* when anchored in the roads, and still more when on the high seas, dealt such fearful destruction, a fact quite inexplicable on the contagionist theory manifested itself. Of the (about) sixty officers serving on board, from the septuagenarian admiral to the youngest midshipman, not one was even ill." On their imperative return to Varna, the crew were accommodated in transport ships, while all the officers, of their own free choice remained on board the *Britannia*, "partly," as Professor von Pettenkofer's informant says, "to restore the courage of the men, partly out of convenience; and even then not a soul of them was sick. I slept in an empty cabin on the lowest deck, in spite of the physician's warning," and nothing came of it.

Now for the cause why on board the *Britannia* the cholera was so severe, while on board the *Trafalgar* and the *Queen* it was so very mild. Had the outbreak in the ship been due to the presence of cholera patients, cholera linen, and so forth, this circumstance was common to the other vessels. Dr. Milroy has already tried to explain the excess of the malady in the *Britannia* from another cause, which certainly might have had effect, not on the specific infection, but on the development of the disease in the individual subject. At night, after the numerous cases of diarrhœa and cholera had counselled removal to the high seas, it was necessary to shut the lower portholes. According to him, the men seemed poisoned with the foul air they breathed all night through. A more striking example, in his opinion, of the deadly effects of impure air in the time of an epidemic, and of the infallible means of checking them, could not be conceived. The immunity of the officers, he thinks, on this occasion was doubtless a consequence of the ampler breathing space they had at command. This explanation Professor von Pettenkofer admits to be one which must satisfy the practical physician whenever it is his business to find an opportune cause for an unexpected occurrence. "I, too," he says, "hold foul air as injurious, but not as sufficient to account for such an explosion of cholera. In the case before us we must not forget that it was on account of her heavy sick list that the *Britannia* had already sought the high seas. Then we must bethink ourselves of those cases in which, despite the most liberal ventilation, the cholera could not be got rid of—as witness the well-known epidemic on board the *Windsor Castle*. Finally, it would still have to be investigated whether there were not other ships which, coincidently with the *Britannia*, were heavily visited with cholera, and which had the lower portholes open. My informant has set my mind completely at rest on this point, that the crew of the *Britannia* were not inhaling such foul air as Dr. Milroy's report made me suppose."

Professor von Pettenkofer's eye-witness (a young naval officer on board the *Britannia*, who lived and served throughout the whole visitation) corrects another erroneous assumption. The professor had concluded that the shutting of the lower portholes was caused by stormy weather. It was not so. On the day of the departure from Kavarna Bay a calm came on; instead of the wished for cool breeze, the sun blazed down on the cholera-stricken vessel. In addition to this a ground-swell occurred, causing long, oily-looking waves without wind. As a consequence, the ship swayed so that the hatches of the lowest cannon-deck, where the men slept, had to be shut. And now came the terrible night in which fifty-eight men died—a night without wind, without a pulsation in the sultry air. Storm there was none; would that there had been! The closing of the hatches had no influence in producing the mortality, for, on account of the heat, the men did not sleep in their hammocks, but were allowed to lay themselves down where they pleased, the majority bivouacking in the open air on deck and on planks. The physicians themselves had given the order, and it was precisely in the open air that most of the men died. It may be remarked that the *Ville de Paris*, which remained in the roads, lost as many as the *Britannia*, though her hatches and portholes were wide open.

The bad air theory, from the shutting of these ventilators, thus falls to the ground. Equally futile, as explaining the cholera explosion, is the contagion theory. That a cholera patient with his evacuations or cholera-linen came on board accounts for nothing, for many other ships had the same thing occurring to them, and no evil results followed. But perhaps the infective matter was brought to the *Britannia* in the food or drinking-water used only by the crew. On this point Professor von Pettenkofer's informant is decisive: "Provisions came daily from shore, even during the epidemic, when we were fifteen leagues from Kavarna Bay, but the officers ate the same meat, the same vegetables, the same fruits as the men. The only difference was that the crew drank rum-and-water and the officers wine; while in the drinking-water no distinction was observed." Nor was the ballast from the shore a vehicle for bringing the infective matter on board the *Britannia*, which used neither sea-sand nor rubble, but, as on all English vessels of war, only iron—the so-called pig-iron—in square pieces, wedged together in the lowest ships spaces, and never disturbed.

Nothing remains to account for the outbreak but the previous communication of crews and officers with the shore. Professor von Pettenkofer again quotes his eye-witness:—"The sick, not only on board the *Britannia*, but on all the other vessels of the allied fleet, had, before the cholera visitation, while we lay in Varna, regular communication with the land, and our men—there is no denying it—frequented the same boozing kens and places of lascivious resort, which cropped up in the town like mushrooms." As the *camaraderie* of regiments on land and ships' crews ashore leads to this—that the one will patronise one place of rendezvous, and the others by preference another, so, concludes Professor von Petterkofer, "we may assume that the cholera locality on shore was the seat and the occasion of infection (*Infectionsgelegenheit*), that individual and specially infected resorts were haunted by the men from one ship more than by the men from another, and that many lingered in this or that house oftener or seldom, for a longer time or a shorter." He leaves it an open question whether the infective matter engendered in the locality was inhaled by the men or whether they took it in what they ate or in what they drank. If, he thinks, we consider the facts without prejudice, we shall find no possible proof of the contagion theory, but only that of the localistic theory (*localistische Anschauung*) of cholera diffusion and infection.

In emigrant ships the manifestation of cholera obeys the same laws as in war-vessels, and the question to ask is, where those who fall ill on board have been on land before embarking. "My attention has just been drawn," the Professor says, "to the fact that 11 cases which occurred in the *Westphalia*, between Hamburg and New York, from Aug. 27th to Sept. 10th, 1873, belonged all of them exclusively to two German families, and that quite as severe an epidemic as that on board the *Britannia* was possible, had the majority of the other passengers before their embarkation lived together or been in similar circumstances with the said two families." That this here and there actually occurs is proved by the epidemic outbreaks exceptionally taking place in emigrant ships. That the *Britannia* as a vessel was not a focus of infection may be seen from the 60 gallant officers who remained unaffected on board.

Prof. von Pettenkofer hopes some one of the European maritime powers, during the cholera invasion, will organise a commission to make minute investigations on the occur-

Digitized by Google

rence of the disease in ships, and on any etiological momenta antecedent to it, although, he says, a similar proposal made more than ten years ago met with no response.

THE CHOLERA EPIDEMIC.

ALTHOUGH there has been no material extension of the epidemic at Marseilles and Toulon, yet the steady recurrence day by day of some eight to twelve deaths in the former and of some two to six deaths in the latter place is sufficient to cause anxiety, especially in view of the continuance of the almost tropical weather on the Mediterranean coast. With the advent of colder weather a more rapid diminution of the outbreak might reasonably be anticipated. A considerable number of places in the departments of Bouches du Rhone, Var, Basses Alpes, &c., are continually reported as having suffered from cholera deaths, but the facts that no large mortality occurs in any one place and that localities alleged to be infected one day are not heard of again gives reason to hope that some of the attacks are only of the sporadic type, and that the others fail to get that hold upon the places in which they occur which is so characteristic of Asiatic cholera during the period of its diffusion. Some recent rumours as to the extension of the epidemic to the north of France were evidently not justified. In Italy the disease has extended, and deaths are reported from the provinces of Campo Basso, Cuneo, Parma, Massa Carrara, Port Maurice, Cosenza, and Turin. None of the outbreaks are on a wide scale, but the Italian Government has despatched large bodies of troops into the provinces of Campo Basso and Cosenza, for the purpose of again trying the effect of the sanitary cordons which have hitherto so signally failed.

The account which has been published as to the alleged death from Asiatic cholera in Birmingham fully justifies the caution which we gave last week as to the inexpediency of basing alarming rumours on a single attack, which might exhibit symptoms which, though resembling those of true cholera, are also often met with in the severer cases of the sporadic disease. In the temporary absence of Dr. Alfred Hill, whose mature judgment, based on a lengthened experience, would have been opportune had it been available, the Mayor has sought the advice of Mr. Waterson, surgeon to H.M. Prison at Birmingham, and on his authority it is officially announced that the case was simply one of English cholera.

OFFICIAL CHOLERA REPORTS.

In view of the prevalence of cholera on the Continent and of the possible invasion of this country, the Local Government Board have issued a reprint of a number of reports which have at intervals been made to them and to the Privy Council Office, together with the comments which have been made concerning them by their several medical advisers, including Mr. Simon. Dr. Buchanan introduces the set of papers by a preliminary report, in which he sets forth the object of the reissue, it being intended both to exhibit the doctrines concerning cholera in Europe which have been continuously held by the principal medical advisers of the English Government, and further, to indicate the local conditions provocative of cholera in England. For these purposes the publication has considerable value, for the principles which Mr. Simon and his successors have so long and so successfully laboured for are fully set out, and the detailed reports by Mr. Netten Radcliffe, Dr. Buchanan, and the late Drs. Parkes and Seaton, on actual outbreaks, including some of considerable historic importance, cannot fail to be extremely helpful in guiding those who may at any moment have to conduct similar inquiries in their own districts. The publication, which can be procured as an official paper for a few pence, deserves a wide circulation amongst medical officers of health.

QUARANTINE AND INFECTED PORTS.

THE *London Gazette* of the 15th and 19th inst. contains notifications to the following effect:—

All merchant vessels whatsoever arriving at Greek ports, unless furnished with a visa of the Greek consular authorities, will be subjected to a quarantine of five or of eleven days, at the discretion of the sanitary authority.

The Italian coast, from the French border to Civita Vecchia, has been proclaimed under suspicion of cholera. The ports of the Gulf of Genoa have been declared by the Portuguese Government to be infected with cholera.

At Buenos Ayres, eight days' quarantine will be imposed on all vessels arriving from Toulon and Marseilles or any other port in which cholera has shown itself; should a case of the disease have occurred during the voyage, the quarantine will be extended to fifteen days.

Vessels arriving at the Danish West India Islands will be subjected to strict investigation, and a quarantine of fourteen days imposed on those on which a suspicious case of cholera has occurred.

A quarantine of sixty days or more is imposed on arrivals at Ship Island Harbour, Mississippi, from cholera-infected ports.

The term of quarantine for ships arriving at Sicily and Sardinia has been increased to twenty-one days.

THE BRITISH PHARMACEUTICAL CONFERENCE.

THE meeting of this Conference, on the 13th instant, was devoted to the reading and discussion of papers, the programme containing a total of twenty-eight contributions.

The alkaloid value of commercial and of wild belladonna was the subject of a final report by Mr. A. W. Gerrard; that of atropa belladonna the subject of a report by Messrs. W. R. Dunstan and F. Ransom; and Mr. T. J. Hasselby contributed some notes on the growth of belladonna and hyoscyamus; English rhubarb was the subject of two papers by Mr. W. Elborne; and Messrs. W. R. Dunstan and F. W. Short contributed a report of an investigation, aided by the Research Fund of the Conference, on the chemistry, botany, and pharmacy of the strychnos nux-vomica.

The suggestion that preparations of nux-vomica should be standardised was followed by papers on the standardising of pharmaceutical preparations, by Mr. G. F. Schacht and Mr. D. B. Dott. In the course of his paper Mr. Schacht said that suggestions had recently been made for standardising some of our galenicals. He considered these suggestions to be unwise, and mainly because they involve an assumption of knowledge concerning them that is not possessed. He regarded remedies in this connexion as divisible into two classes—first, definite chemical substances and their diluted forms, which lend themselves naturally to standardising, and cannot be too exactly standardised for employment in medicine; and, secondly, remedies of mixed and variable constitution. These cannot, with our present knowledge, be standardised in a way to convey the truth as to their medicinal potency, and therefore must form a class of more or less vague medicinal value. In the progress of the art of medicine from empiricism to science, it is probable much more exact knowledge concerning substances occurring in the latter class will be arrived at, and then such remedies may properly pass into the former class. But the work connected with this progress is chiefly medical work, and pharmacy can only follow and assist; it certainly cannot pretend to lead. Mr. Dott remarked that in order to standardise preparations of a drug it was necessary that the amount of active principle or principles be capable of accurate and reasonably easy determination. This rule excluded a large section of the materia medica, as there is a host of drugs whose active principles are unknown or incapable of exact determination. It is only practicable to standardise preparations of those drugs which readily yield their active principles in a state of comparative purity. An objection to standardising pharmaceutical preparations was that the operation could only be safely performed with an amount of knowledge and experience which would not be always available. A serious error in analysis might lead to greater variations in strength than the pre-standardisers ever dreamt of. Taking all the facts into consideration, no general system of standardising ought to be introduced into the British Pharmacopœia.

After papers had been read by Mr. W. Martindale on the composition of seidlitz powders, and by Mr. T. Greenish on the pharmacy of linseed, Mr. W. Southall reported the result of a microscopical examination which he had made of a specimen of a fungoid plant, the Tasmanian native bread. He came to the conclusion that the plant may be considered a mycelium or the sclerotioid-mycelium of a fungus of which

Digitized by Google

the other stages of growth have not yet been discovered. The specimen weighed when fresh 37 lb.

The composition of gray powder, of blue pill, and of blue ointment was treated by Messrs. M. Dechan and T. Maben; sesame oil as a basis for lead plaster was further reported upon by Mr. T. Maben, whose later experiments led him to form a more decided opinion in favour of it than he could have given a year ago; commercial Peruvian balsam was reported upon by Mr. P. MacEwan, who found twelve samples to be pure; Mr. T. S. Dymond compared the two processes of testing the amount of diastase in extract of malt, which is becoming a popular remedy; Mr. J. R. Hill called attention to the possibility of pharmaceutical preparations being contaminated by the copper of the vessels in which they are prepared; Mr. R. Wright recommended the use of hydrochlorate of quinine instead of the sulphate of quinine in the preparation of the tincture; and the presence of iodine in cod-liver oil and other marine products was reported upon by Mr. E. Stanford, who stated that in Anglo-Portuguese oysters the proportion was too small to be of use. Sulphurated lime having come into use as a remedy for boils, Mr. T. Dymond compared the different processes of making it; Mr. D. Hooper contributed elaborate analyses of some old cinchona barks.

The papers disposed of, it was determined to hold the next meeting at Aberdeen. In the election of the officers Dr. J. C. Thresh of Buxton, was associated with Mr. Plowman of London in the honorary secretaryship. Mr. J. B. Stephenson of Edinburgh was elected President and Mr. A. Strachan of Aberdeen local secretary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Fever and Diphtheria in the Romford Rural District, by Dr. PARSONS.—The rural portion of the Romford Union contains a population of 21,862, and it has suffered from several outbreaks of fever and diphtheria during recent years. In the end of November, 1883, enteric fever appeared at Victoria Cottages, Dagenham,—a row of twenty-nine cottages and a public house lying in an open situation. Here conditions very typical of the district were found to exist. Slop-water goes into cesspools overflowing into an offensive ditch, and cesspit privies prevail. At either end of a row, the soil of which is thus in danger of being befouled, is a well, and a wet boggy site discoloured with black fetid matter having been selected, it was found that paraffin oil poured down here found its way within three days into the well, the water from which on analysis showed a high proportion of nitric acid and albuminoid ammonia; the sample also exhibited microscopic constituents probably derived from household waste. All the cases of enteric fever, eleven in number, occurred in twenty-three houses using this water, the remaining seven escaping. Again, in the winter of 1882-83 a considerable outbreak of enteric fever took place at Great Ilford, fifty-nine persons in thirty-five households being attacked. The medical officer of health aptly describes Ilford as "ripe for the outbreak of a serious epidemic of typhoid fever, should the germs of the disease be introduced, as a corn-stack is ripe for the flames should a lighted match be applied to it." But little is known of the sewers there, except that they are unventilated; cesspool drainage also exists, leading to soakage and overflow into a gravelly soil, with consequent nuisance on the surface. No proper precautions exist to prevent the escape of foul air into houses, either from drains or cesspools; and so-called waterclosets without water also exist. It is possible that at the onset the disease had its origin in an infected milk-supply. The date, however, at which Dr. Parson's inquiry was made prevented the circumstances as to the earlier history of the cases being submitted to an exhaustive examination. But it is clear that, so far as diffusion is concerned, the faulty sanitary conditions we have adverted to, and especially the facilities for the escape of infected sewage exhalations into and about houses, must materially have conduced to increase the outbreak. Enteric fever also prevailed at Barkingside in the autumn of 1881, in a locality where drinking-water is so scarce that it has to be imported by cart, and where the supply for so-called washing purposes is from a sewage-polluted brook. As regards diphtheria, independent groups appeared in and about Chadwell-heath, Dagenham, in the winter of 1883-84, the locality being one where cesspools overflow into nearly stagnant roadside ditches. Other outbreaks, apparently due to importation, or at times associated with cases of scarlet fever and of so-called "croup," occurred in other localities. Of Dagenham, where some of these cases took place, it is stated that most of the houses are old and dilapidated; there is no sewerage; the house-slops run into ditches, cesspools, or pits; sewage nuisances are frequent in the neighbourhood of houses; the privies are ill-made and offensive, and are too near houses; and water is obtained from wells sunk in a porous gravel-bed, and which are suspiciously near to privies, cesspools, and other sources of contamination. Conditions such as these have now existed for a long time in this rural district, and although small works of improvement have been carried out from time to time, no measures of a comprehensive character have been adopted. The authority have, however, now approved of a work of sewerage to include Ilford, Chadwell-heath, and Barkingside. In connexion with the diphtheria it may be noted that much of the district lies to the north of the Thames, where it is bordered by a belt of alluvial marshes about a mile wide; to the north of this is an extensive plain of gravel, resting on London clay;—and still further north the district is hilly, the soil being composed mainly of the London and boulder clays.

Diphtheria and Typhoid at Calne, by Dr. BLAXALL.—So far as diphtheria is concerned, this report gives an account of a somewhat large prevalence of the disease which, in so far as its spread is concerned, had mainly to do with intercommunication between sick and healthy at one of the elementary schools in the place, and also as regards one portion of the outbreak, with infection conveyed through a servant girl. The report does not succeed in unravelling the mystery which so often attaches to first cases of this disease, but it is able to show once again the imperative importance of having at hand some available means for the isolation of the first attacks which come under observation. A want of definite regulations to govern school attendance with a view to guard against children being sent to school in an infective state was also matter of comment, and this subject is one which unquestionably calls for some general attention in the future, especially in connexion with refusal to re-admit children from infected localities and houses, except on a medical certificate of freedom from danger. The outbreak of enteric fever was a localised one, brought about in the main by faulty drainage arrangements, and one of the principal recommendations attached to the report relates to the need for action to remedy the defects both in the sewerage and drainage of the place. Calne was inspected by Dr. Blaxall in 1874, and although improvements have been made since that date, yet much remains to be done as regards the system of cesspit privies, the systematic and frequent removal of refuse, and the special nuisances attaching to pig-keeping in a town where some 300 pigs are daily slaughtered.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 16th inst., 5781 births and 4052 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the three preceding weeks had declined from 24·9 to 21·9 per 1000, rose last week to 24·1. During the first seven weeks of the current quarter the death-rate in these towns averaged 22·8 per 1000, against 20·1 and 20·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 17·4 in Bristol, 18·5 in Derby, and 18·8 in Huddersfield. In the other towns the rates ranged upwards to 30·6 in Oldham and in Portsmouth, 31·1 in Bolton, and 43·3 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily declined in the four previous weeks from 1257 to 911, rose again last week to 1108; these included 789 from diarrhœa, 103 from measles, 68 from "fever" (principally enteric), 68 from whooping-cough, 49 from scarlet fever, 21 from diphtheria, and 10 from small-

Digitized by Google

pox. These diseases caused the lowest death-rates in Huddersfield and Bristol, and the highest in Norwich and Wolverhampton. The highest rates of mortality from diarrhœa were recorded in Leicester, Norwich, and Wolverhampton; from measles in Wolverhampton and Blackburn; from whooping-cough in Sunderland and Derby; and from scarlet fever in Wolverhampton and Sheffield. Of the 21 deaths from diphtheria in the twenty-eight towns, as many as 19 were recorded in London. Small-pox caused 9 deaths in London (exclusive of 3 metropolitan cases registered outside Registration London), and 1 in Sheffield. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which in the five previous weeks had declined from 1368 to 810, further fell to 640 on Saturday last; the cases admitted were 64, against 66 and 110 in the two preceding weeks. The Highgate Small-pox Hospital contained 37 patients on Saturday last, 6 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which in the two previous weeks had been 198 and 187, further declined to 162, and were 14 below the corrected average. The causes of 92, or 2·3 per cent., of the 4052 deaths last week in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Sunderland, Norwich, Derby, and Cardiff. The largest proportions of uncertified deaths were recorded in Blackburn, Oldham, and Hudderfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·6 and 20·7 in the two preceding weeks, was again 20·7 in the week ending the 16th inst.; it was 3·4 below the average rate during the same period in twenty-eight of the largest English towns. The rates in the Scotch towns last week ranged from 13·4 and 13·6 in Paisley and Greenock, to 23·5 in Perth, and 25·9 in Glasgow. The 499 deaths in the eight towns included 51 which resulted from diarrhœal diseases, 29 from whooping-cough, 9 from scarlet fever, 9 from measles, 6 from "fever," 5 from diphtheria, and not one from small-pox; in all, 109 deaths were referred to these principal zymotic diseases, against 85, 95, and 114 in the three preceding weeks. These 109 deaths were equal to an annual rate of 4·5 per 1000, which was 2·1 below the mean rate from the same diseases last week in the twenty-eight English towns. The deaths from diarrhœal diseases, which had been 40 and 51 in the two previous weeks, were again 51 last week, and exceeded by 8 the number in the corresponding week of last year; 27 were returned in Glasgow and 7 in Edinburgh. The rate of mortality from diarrhœa in the Scotch towns did not exceed 2·1 per 1000, while it averaged 4·7 in the large English towns. The 29 fatal cases of whooping-cough were within 2 of the number in the preceding week, and included 20 in Glasgow and 4 in Edinburgh. All the 9 deaths from scarlet fever were recorded in Glasgow, where 6 of the 9 fatal cases of measles were also returned. The deaths from "fever" showed a further increase upon recent weekly numbers, while those from diphtheria showed a decline of 2 from the number in the preceding week. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns were 64, against 66 and 65 in the two previous weeks, and were 8 below the number returned in the corresponding week of last year. The causes of 77, or more than 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 23·0 and 22·4 per 1000 in the two preceding weeks, rose to 24·2 in the week ending the 16th inst. During the first seven weeks of the current quarter the death-rate in the city averaged 22·0 per 1000, the rate during the same period being equal to 23·0 in London and 17·0 in Edinburgh. The 163 deaths in Dublin last week exceeded by 12 the number in the previous week, and included 33 which resulted from the principal zymotic diseases, against 16, 22, and 23 in the three preceding weeks; of these, 22 were referred to diarrhœal diseases, 6 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 1 to whooping-cough, and not one either to small-pox, measles, or diphtheria. These 33 deaths were equal to an annual rate of 4·9 per 1000, the rate from the same diseases being 5·1 in London and 2·7 in Edinburgh. The deaths referred to diarrhœa, which had been 11 and 8 in the two previous weeks, rose to 22 last week. The fatal cases of scarlet fever corresponded with the number in the preceding week, while those of "fever" and diphtheria showed a decline. The deaths of infants considerably exceeded the number in the previous week, while those of elderly persons were below the average of recent weeks. The causes of 30, or more than 18 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-Major E. C. Markey, medical officer in charge of the Cambridge Hospital, Aldershot, is held in readiness for immediate embarkation for Egypt. Brigade-Surgeon E. G. McDowell, C.B., has been ordered to Aldershot to assume charge of the Cambridge Hospital.

ADMIRALTY.—Fleet Surgeon Robert Nelson has been appointed to the *Achilles*.

ARTILLERY VOLUNTEERS.—The Tynemouth: Acting Surgeon William Pope Mears, M.D., from the 1st Northumberland and Sunderland Artillery Volunteer Corps, to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon Charles Holttum is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE DEMONSTRATION OF THE BACILLUS LEPRÆ.

To the Editor of THE LANCET.

SIR,—The discovery of bacillus lepræ, though made some years before that of bacillus tuberculosis, has not been put to the same very practical use in diagnosis that immediately followed the discovery of the latter bacterium. The reason for this lies in the comparative difficulty hitherto attending the demonstration of the parasite of leprosy. To show it, it has been necessary to excise a portion of affected tissue—an operation naturally objected to even by a leper; and afterwards the tedious processes of hardening and section-cutting have to be gone through prior to the final staining, washing, and mounting; and even then, when the preparation, the result of so much labour, is under the microscope, it sometimes, especially to the untrained eye, may require a considerable exercise of faith to recognise in the patches and ill-defined streaks of colour the bacillus. I have shown such specimens to friends, and at times their smiles were more indicative of incredulity than conviction.

By a method I now adopt, the bacillus can be demonstrated as easily, rapidly, and perfectly as can that of tubercle, and the preparations are so clear that on examining them the most thorough sceptic is immediately converted to a belief in the bacillus lepræ. I proceed as follows:—A leper tubercle or infiltrated patch is selected and the whole or part of it included in the jaws of an ordinary thin-bladed pile clamp. The tightening of the clamp has the effect of driving out all the blood from the included tissues, and the tubercle, from being dirty red or purple, becomes like yellow wax. The hold of the clamp is maintained at a degree of tightness sufficient to keep up this state of anæmia, and at the same time the centre of the included mass is pricked with a needle or sharp knife. From the puncture a droplet of perfectly clear fluid exudes, and is to be transferred to one or more cover-glasses, each cover-glass being smeared with rather a thick layer of the leper juice. The cover-glasses are then dried, stained, washed, and mounted in the ordinary way. The Weigert Ehrlich method I have found give good results. Under the microscope slides so prepared show bacilli in prodigious numbers, both free and in dense bundles packing the leper cells. The diagnosis of leprosy from the juice of

Digitized by Google

the leper tubercle is in this way made as easy, expeditious, and visible as is that of tubercular phthisis from sputum.

Trusting that this hint may be of service to those interested in leprosy and its bacillus,

I am, Sir, yours truly,

Hong Kong, China, July 9th, 1884. PATRICK MANSON.

THE CASE OF JOSEPH JAMES DONNELLY.

To the Editor of THE LANCET.

SIR,—Dr. Hughes Bennett finishes a very instructive letter in this day's LANCET upon the case of Joseph James Donnelly by asking a question, which I am very glad to be able to answer if you will grant me space in your columns for the purpose.

Dr. Bennett writes:—"The public have a right to be informed whether this individual is for the future to be considered as a lunatic, and consequently as an innocent man, or whether he is to undergo penal servitude for life as a malefactor." Dr. Bennett will, I am sure, be glad to learn that Donnelly was admitted into the epileptic ward of this asylum on Monday, the 4th inst., where, if Dr. Bennett should ever be in this neighbourhood and should have half an hour to spare, he may, if so inclined, renew his acquaintance with his quondam patient, and at the same time afford me the pleasure of showing him the general arrangements of the asylum.

It is very justly pointed out by Dr. Bennett that, Donnelly being what in his letter to you he describes him to be, two things of a nature to be regretted have happened in his case. The first is, that he was permitted to have the opportunity of killing his sister; and the second is, that he was afterwards tried and sentenced as if he had been a responsible malefactor. Now, although no one would, I think, have the hardihood to hazard the assertion that our statutes relating to lunatics are perfect, or that the resources of civilisation have been exhausted with respect to our modes of procedure in the treatment of these unfortunate persons, still we are, happily, not compelled to own that there is absolutely nothing that could be done, in a similar case in the future, to avert the occurrence of similar unfortunate incidents.

With respect to the means for the possible prevention of the recurrence of similar acts of homicidal violence, I would ask your permission to point out that any medical gentleman who possessed information similar to that which Dr. Bennett possessed as to his patient, at the time of discharging him from hospital, would be taking a legal and justifiable course if he were to address a letter to the relieving officer of the parish to which the patient belonged, stating the circumstances, together with his opinion of the patient's mental condition. Upon the receipt of such a letter every relieving officer of a parish is bound by statute (16 and 17 Vict., chap. 97, sect. 68) to make inquiry into the case.

With respect to the second point, the suggestion that I would venture to make is, that if any medical gentleman should ever be in possession of any facts relating to the mental condition of any person committed for trial upon a charge of murder, and should be in any doubt or difficulty as to the right course to take in the matter, he may, if so disposed, address a letter to me stating the facts, and I will, very gladly, charge myself with the duty of taking steps for bringing before the court and the jury such facts as may reach me in this way. The only stipulations I would make are, that the information should reach me sufficiently long before the trial, and that the facts should either be within the personal cognizance of the writer or be capable of proof by witnesses.

With the view of disarming criticism beforehand, will you permit me to add that I do not offer these suggestions as if I thought that they contained the whole duty of man in the matter, but that I offer them only as possible aids to those in doubt.

I am, Sir, your obedient servant,

W. ORANGE.

Broadmoor Criminal Lunatic Asylum, Aug. 16th, 1884.

To the Editor of THE LANCET.

SIR,—As you do me the honour to refer to a letter of mine in your leading article of the 9th inst. on the above case, I trust you will allow me to state, in as few words as possible, why I find myself unable to agree with some of the remarks in that article.

First of all, you seem to doubt the propriety of interfering to prevent the execution of the capital sentence when once it has been pronounced; you "think that matters of this sort should be dealt with finally at the time of trial, or rather before it," and although you allow Donnelly's to be one of the exceptional instances which call for inquiry, you state in general terms that you do not "think it expedient, in the interests of public safety, that there should be this last chance of escape open to criminals." My answer is that cases occur not unfrequently in which, from the poverty of the accused and the peculiarities in our English methods of judicial procedure, the arguments in support of the plea of insanity are imperfectly brought out during the trial. Take, for example, this very case. Donnelly's friends were too poor to provide him with any sort of legal assistance, so that had not a member of the Bar kindly undertaken the defence at the request of the presiding judge, the poor fellow would have been left without anyone to plead his cause. As it was, his counsel entered upon his task under every conceivable disadvantage; no defence had been prepared, no witnesses had been summoned on the prisoner's behalf; and as the prosecution did not happen to produce the one witness, Dr. Dreschfeld, whose evidence was likely to tell in the man's favour, it was impossible to elicit, in cross-examination, the facts which were necessary in order to sustain the plea. It is perfectly evident, therefore, that the trial could not, in the nature of things, be a satisfactory one; and to my mind it would be horrible if a decision, arrived at under such circumstances, should be held to be irreversible.

If it be asked why means were not taken to interfere in the matter before or during the trial, I reply that interference by persons not directly concerned in a case that is *sub judice* is generally supposed not only to be impolitic but absolutely reprehensible. It seems to me that I adopted the only course open to me; I abstained from interference until the trial was over, and until there was imminent danger of a deplorable miscarriage of justice. That the case was one that needed revision is proved by the fact (of which, of course, I was not aware when I wrote to the local papers) that the Government had already sent two medical inspectors to report on the case, and that in consequence of their report the man has been reprieved during Her Majesty's pleasure.

But there is a still more important point in your leading article on which I am compelled to differ from you. You compare the condition of an epileptic maniac with that of a patient rendered irascible and peevish from an attack of gout, or from phthisis in a certain stage, or from the approach of certain changes in the sexual life. In my opinion the two conditions are incomparable. In the case of an epileptic maniac, his acts of violence are done unconsciously, and therefore are uncontrollable; in all the other cases mentioned, acts of a similar nature would always be done consciously, and would simply be the result of uncontrolled temper. Epileptics like Donnelly have no control over their actions during the maniacal paroxysm, and no recollection of them when it is over. They are therefore legally and morally irresponsible, and no effort can be too great to prevent their being systematically treated as criminals.

I remain, Sir, yours very truly,

CHARLES J. CULLINGWORTH, M.D., M.R.C.P.,
Lecturer on Medical Jurisprudence at the Owens
August 13th, 1884. College, Manchester.

P.S.—As my letter happened to be too late for insertion last week, may I be allowed to add a postscript, expressive of the pleasure with which I read Dr. A. Hughes Bennett's letter in THE LANCET of last Saturday? I entirely concur in the sentiment to which he has given such forcible expression. With regard, however, to the mismanagement of the prisoner's defence, the above letter will show that our system of preparing cases for trial is more to be blamed for the extreme unsatisfactoriness of this inquiry, than the very able advocate who kindly undertook the defence at the last moment, without having received any instructions, and who was consequently at an enormous disadvantage throughout the case.

THE CHOLERA IN FRANCE.

To the Editor of THE LANCET.

SIR,—Before leaving for Paris, I send you a line to say that on visiting the hospitals, both of Toulon and this place, I was agreeably surprised to find all the patients either con-

Digitized by Google

valescent or in the stage of consecutive fever in which the intra-peritoneal injections were not called for. No admissions in the algide stages of this disease presented themselves whilst I was there. For some time, however, these injections into the peritoneum have been exercising the minds of practitioners here, through quotations from THE LANCET having found their way into the foreign press; and since Dr. B. W. Richardson's first essay in 1854 many authors appear to have written on the subject. The chief difficulty seems to have been the want of directions for the employment of the method. In tapping for dropsy, the volume of ascitic fluid would protect the intestines; but in injecting the peritoneum for other diseases, it would seem necessary, as Dr. Richardson has done, to make a small lancet incision and scratch down to the peritoneum, and then push in a blunt cannula. Such a cannula, blunt at the end, with an eyelet like a catheter at one side, I have left with Dr. Duranty, one of the chief physicians of the cholera hospital established at the Palace of "Pharo," at the entrance of the harbour here; and Dr. Bassano, one of the house-surgeons, and the Doctor himself, have promised to give me careful details of any cases which they may be able to treat by intra-peritoneal injections. All seem anxious to try them, intra-venous injections neither having succeeded in this epidemic, nor being, unless with exceptional apparatus, unattended with risk. The almost sudden influx of fluid by the veins seems to be unfavourable. I also strongly recommended the injection of the subcutaneous cellular tissues with warm water, so as to produce artificial anasarca, for both cases of dropsy and anasarca have been known to recover when attacked by cholera, apparently through the absorption of their effusions. To Dr. B. W. Richardson, it appears, we are indebted for this method, though others may have thought of it independently. Drs. Coney and Purves have recommended vesical injections, but Dr. Richardson, who tried this long ago, did not find the absorption to be satisfactory. Besides, so dangerous is the reabsorption of urine, that the catheter has often to be employed.

The epidemic seems to be passing away. The deaths registered are chiefly of cases admitted long ago in the stage of secondary fever. The admissions seem now to be few.

Dr. Koch has recommended, I hear, the non-watering of the streets, as he believes desiccation kills the "microbia."(?)

All the medical officers, sisters, and attendants, including ladies of rank, the British consulate, chaplains, &c., display the utmost courage and devotion.

I am, Sir, yours truly,

CAMERON MACDOWALL, F.R.C.S. Edin.,
Marseilles, August 1st. Brigade Surgeon, Bombay Army.

P.S.—To show you how extremely difficult it is to introduce any new treatment of disease, I send you a copy of the following telegraphic answer (the original telegram I have had to send to the India Office) to my inquiry—if, since I left Toulon and Marseilles, it has been possible to make any trial of "intra-peritoneal injections" with the apparatus which I left there? The answer was as I expected from what I saw at the hospitals, where no cases in the algide stage were admitted during my stay. It was to this effect: "Not yet. Waiting for favourable case." This I received on Friday from the interne or house-surgeon, Dr. Bassano, I drank Toulon and Marseilles water, and may say that I suffered from diarrhœa before going there. This diarrhœa increased so much at Marseilles that I was obliged to take one-drachm doses of bismuth in mucilage before it yielded on the third day. Like ipecacuanha in acute dysentery, small doses are useless. After burning most of my clothing, I endured a good ten days' quarantine in the north of France before coming to England. In conclusion, I may be permitted to say that this epidemic, which has been monstrously exaggerated in public opinion, is comparatively mild. The statistics of the Pharo Hospital at Marseilles show that considerably more than half the cases recovered. If imported by the transport *Sarthe*, it would appear that the forty days' sea voyage may have attenuated considerably the virus, or else, as I have thought ever since I saw cases in Liverpool, the epidemic coming by sea is less formidable when it arrives than when travelling by land *viâ* Russia &c. To those who blame the sanitary state of Toulon and Marseilles, I would point out the very extraordinary difficulties of draining the places into the tideless Mediterranean. The upper town is built almost entirely on rock, the lower on piles, and water is found at a few feet. Closed cesspools are excavated under the new houses, which are periodically emptied in the night by steam power; for it must be remembered that even in Paris, and according to very generally approved ideas, no sullage from waterclosets is allowed to enter the drains, which carry into the River Seine only kitchen and surface waters. In the lower town such cesspools or "fossées" are impracticable, and receptacles are carried down at night into each street to be taken away and brought back empty. I believe a system of covered surface drains has been spoken of; but then, as in Marseilles, the docks will become foul, as there is no tide, unless the drains be carried far out to sea. There would be no deficiency of water, for clean streams run down the gutters of almost every street. It is turned on periodically.

OUTBREAK OF CHOLERAIC DIARRHŒA AT CLAYTON-LE-MOORS.

To the Editor of THE LANCET.

SIR,—On Saturday, Sunday, and Monday, the 2nd, 3rd, and 4th inst., between 100 and 150 persons of all ages were taken ill in the above township with vomiting and purging, and at the same time almost as many were attacked in the adjoining parish of Rishton. Having treated eighty-five of these cases myself during the past week, it may be interesting to your readers to report concerning the causes and symptoms of the outbreak, the treatment adopted, its infectious or non-infectious nature, and the conclusions at which I have arrived generally.

In all cases except two I traced potted meat from one pork butcher. It was made from beef, pork, and pig's head, and those who had partaken largely were affected most.

The symptoms were the same in all, with varying degrees of intensity. They were vomiting and purging, pains in the stomach, and, in the worst cases, collapse after a few hours. The vomited matters were first those of the contents of the stomach partially digested, but afterwards of a yellowish or bile-stained watery fluid; whilst the dejecta varied from a brownish to a yellow fluid, and in some cases green, with very foul odour. The tongue was moist, and covered with a white or brownish-white fur, but red at the edges and tip. There were feverish symptoms in the mild cases, but reduction of temperature and coldness of the extremities in the worst.

As regards treatment. In the case of all the adults I prescribed six draughts of an effervescing mixture with half a drachm of a 1-in-20 solution of carbolic acid, fifteen minims of the solution of morphia, and twenty minims of the aromatic spirit of ammonia; one to be given every two hours. In the majority of cases this mixture answered well, but in some of the worst it did not stop either the vomiting or the purging, and it seemed to have a tendency to increase the collapse, no doubt from the depressing action of the morphia upon the respiratory and circulatory centres. In the mild cases sleep was induced with one or two doses, but in the worst the morphia was not retained in sufficient quantity in this form to act as a soporific. In some cases morphia in pill of the strength of one-sixth of a grain answered well in checking the vomiting and inducing sleep, but not in others. In addition to medicine I also ordered brandy and soda-water and milk and soda-water to quench the great thirst which all complained of, and a hot linseed and mustard poultice over the whole of the abdomen. When the above-mentioned effervescing mixture failed, I gave five to ten grains of bismuth, half a drachm of solution of carbolic acid, five to eight grains of hydrate of chloral, five to eight minims of tincture of belladonna, half a drachm to a drachm of glycerine, and water to one ounce, every two, three or four hours, with excellent effect. Many rejected and vomited the soda-water and milk, but all could take and retain water, and particularly port wine and water, better than any other fluid. In cases where there was no vomiting, but only diarrhœa and pain, with feverish symptoms and foul tongue, the following mixture cured in a few hours: three drachms of compound spirit of ammonia, half an ounce or six drachms of solution of carbolic acid (1 in 20), a drachm to a drachm and a half of chloral hydrate, a drachm to a drachm and a half of tincture of belladonna, six drachms of syrup of red poppy, to six ounces of water, half an ounce to be taken every second or third hour. With this mixture also I treated most of the young children

Digitized by Google

affected; of course in reduced doses, and with bismuth in place of ammonia in cases of severe vomiting. I found that suppositories of belladonna and lead acetate greatly relieved the straining at stool when the diarrhœa was abating. Of the stimulants used, I found port wine to agree the best. I believe that in carbolic acid, bismuth, chloral, and belladonna we have an excellent remedy for cases of this kind. I would never in any case give more than half or three-quarters of a grain of morphia either in pill or solution, and am now determined to give the most decided preference to chloral and belladonna, and to discard morphia altogether in the treatment of those severe cases where there is great depression and a tendency to collapse. If carbolic acid, bismuth, chloral, and belladonna prove more efficacious in relieving the vomiting than morphia—as in the worst cases in my hands they certainly did—I think they should rather be used; moreover, there is not the same danger attending the use of them in a system weakened by large losses of fluid as there is in this disease. Again, chloral, whether or not by transformation or chemical change in the blood, has proved of acknowledged efficacy in relaxing muscular spasm anywhere—as, for instance, in convulsions; and hence, I think, its good effects in vomiting and diarrhœa, by exerting a sedative effect upon the diaphragm and the muscular coat of the intestines, and this without much depression of the vascular system. Not so with morphia, in its temporary or evanescent stimulant, and very much more marked depressant, action upon the vascular and respiratory centres. Many of the alleged symptoms of stimulation by morphia I believe to be due to passive congestion of the cerebrum from depression of the circulation, not stimulation. Any depression of the circulation which may result from chloral in the above mixtures is amply compensated for by the belladonna they contain. In some cases of diarrhœa only, the ordinary sulphuric acid and opium mixture, with carbolic acid, answered well, but not so well as ammonia and opium with the same, the reason being, I think, that ammonia, besides being a powerful stimulant, supports the circulation when weakened by losses, by preventing coagulation, whilst acids favour it and have no stimulant properties. I had opportunities of observing the greater and more rapid improvement with carbolic acid than without it in the above mixtures, and am of opinion that it should form a constant ingredient in all diarrhœa mixtures. Of the eighty-five cases, two died collapsed—one, a young collier of twenty-six years, and the other a debilitated man of fifty-one. In both I injected ether subcutaneously to the amount of a drachm or so, but with little or no effect.

Of the infectious nature of the complaint there is but slight evidence in one case, that of a little boy who was continually in the room where one of the worst cases was being nursed, and followed the nurse when the dejecta were being removed. He was taken ill with symptoms similar to those of the others, but with three or four doses of the bismuth, carbolic acid, chloral and belladonna mixture, he was well in twelve hours. All the cases under treatment recovered. Unfortunately none of the meat or stew was examined, as when the cause had been determined all had either been eaten or otherwise disposed of. It seems unreasonable to believe that in two days meat should so far decompose as to cause such terrible sickness, and I am afraid the actual cause must remain a mystery.

A propos of the subject of diarrhœa and choleraic diarrhœa, with the allied one of cholera itself, it occurs to me to speak of Koch's cholera bacillus. It is, I think, quite within the bounds of probability that the bacilli will yet be found in the intestines of patients who have died of diseases other than cholera which have a debilitating action upon the lining membrane of the bowels; and I am of Dr. Roche's opinion that any amount of the bacilli may be swallowed without any evil consequences arising, provided they are well washed.

Finally, I should like to state that, in my opinion, all cases of the nature of those described in this outbreak which present symptoms of a mild character with no depression of vital power should be treated with morphia and carbolic acid combined with ammonia; but that those which present symptoms of collapse should be treated with chloral and belladonna combined with bismuth and carbolic acid; whilst the treatment with ammonia, chloral, and belladonna with carbolic acid should be reserved for those very mild cases which are characterised by diarrhœa with feverish symptoms and nausea, but no vomiting.—I am, Sir, yours truly,

C. R. ILLINGWORTH, M.D. Ed.

Clayton-le-Moors, Aug. 12th, 1884.

CHOLERA: ITS ETIOLOGY AND TREATMENT.

To the Editor of THE LANCET.

SIR,—The cholera is making sad havoc in France, and may any day break out in this country. There are many young medical men who will be perplexed as to its treatment. In 1848 and 1849 many different modes of treatment were tried; and, notwithstanding all the researches that have been made since, there is no fixed plan of treatment adopted by the profession. Many eminent medical men have placed their valuable lives in danger, and worked hard to find a remedy, but the only means known of preventing the disease and checking it are those adopted by Sir William Hunter and his staff in Egypt—isolation and cleanliness, pure air, good water, and especially early medical attendance and good nursing. We have been taught by sad experience that impure water and filth favour all epidemic, endemic, and contagious diseases, and increase their virulence. During the epidemic of 1849 I was requested to take charge of those suffering from cholera and diarrhœa in the townships of Westhoughton, Over Hulton, and Lostock. These townships were very free from stagnant and filthy water, and although I was kept busy night and day for six weeks I had only two deaths from cholera, whereas in the adjoining township of Hindley the water-supply was very deficient, and a brook which received the sewage from houses on both sides passed through the village. The disease in this village was very virulent, and many deaths took place; isolated cases occurred near this spot. A committee sat here day and night to supply blankets, food, and other necessaries. Five medical men were stationed in the village. Isolated cases of death took place in the immediate neighbourhood of the village; other cases were treated successfully in the more healthy parts of the township, where pure air, good water, and proper attention could be had. I found the most favourable symptom was the return of bile in the motions, and I adopted with success the calomel and opium treatment in doses of two grains to one grain or two grains to half a grain for an adult, together with a saline mixture, properly prepared sago gruel and brandy, toast water, coffee or cocoa, or milk-and-water, in equal parts, boiled and allowed to cool. Hygiene is too much neglected. The food and drink are quite as important, and require as much attention, as the medicine, as is also the immediate removal of all discharges. I believe I was instrumental in saving many lives by advice as to preparing and administering food and drink. I am convinced that good nursing is quite as necessary in cholera as medicine. I have seen patients almost pulseless for hours, the legs and arms cold and blue with violent cramp, who, after many hours' rubbing with warm flannels and the administration of gruel and brandy in small quantities, have recovered; some are now living who were in that state in 1849. "Sed tunc quoque unicum in frictione præsidium est; quæ si calorem in cutem evocavit, potest alicui medicinæ locum facere" (Celsus). It has been stated that many of the deaths which take place at Toulon are from the subsequent fever. No doubt some of those cases are attributable to giving opium without the calomel, thus checking the natural secretions from the liver. The acid treatment recommended by the College of Physicians of Dublin was used in many cases in 1849 by some of my colleagues, but was abandoned, and the treatment I adopted resorted to with greater success. Celsus said, "Si post suppressam choleram febricula manet, alvum duci necessarium est; tum cibis vinoque utendum est." Dr. Koch deserves our best thanks for the exertion he has made to discover the cholera germ; but, after all, the only remedies against its spread are cleanliness and temperance, and the clean and healthy state of a country or district or house is the greatest safeguard, the most economical, and the best remedy against cholera.

I am, Sir, yours truly,

Bolton, July 22nd, 1884. JOHNSON MARTIN.

"PHYSIOLOGY OF THE FEET."

To the Editor of THE LANCET.

SIR,—Mr. Allen's regret for representing an opinion of mine on what *should be* as a statement of that which *is*, has not prevented him from pointing out objections to "letting the heel down gradually from the toe," while the words used in my paper were that the foot should reach the ground

Digitized by Google

when nearly flat; just as the caution in the acceptance of a theory which he feels called on to inculcate does not deter him from asserting as a fact that "our distant ancestors walked on all-fours." I took great pains to justify my opinion that, in walking, the toes should first touch the ground. Mr. Allen's letter may pass for a reply to arguments used in mine. As, however, the point involved has an important bearing on the question what proper walking is, it may be added that Professor Michael Foster, as I have since found, holds the same opinion, and that he has paid special attention to the point is shown by his qualifying a statement in the text, that the toe *does* first touch the ground, by a foot-note saying that this is rather as it *should* do. Very recently an intelligent engineer told me that the bare-footed natives with whom he had been engaged in making a railway in Brazil put the front of the foot down first, and hardly touched the ground at all with the heel. These men, he said, were of Portuguese descent, and had exceedingly good feet. Moreover, it is difficult to imagine how Red Indians can walk with their toes turned inwards (whose walking Sir John Burgoyne said should be the model for our soldiers' march) if the heel be directed downwards. So much for Nature. I hear on good authority that high-class teachers of calisthenics in ladies' schools have long taught that in walking the toes should first touch the ground.

I am, Sir, yours truly,

Gloucester, August 18th, 1884. T. S. ELLIS.

*** Here the controversy must close.—ED. L.

"BOGUS AMERICAN DEGREES."

To the Editor of THE LANCET.

SIR,—I notice in your issue of August 16th an extract from *The Times* about the bogus M.D. of the University of Philadelphia. In this district and in the North of England generally, where collieries and ironworks exist, there the impostors of Philadelphia plant themselves, and are a curse to the unfortunate working class, whom they dupe.

I send you the original letter I received from the British consul at Philadelphia. Will you endeavour to bring it under the notice of the medical men in Parliament? Something ought to be done to stop this quackery.

I am, Sir, yours truly,

JOHN C. O'HANLON.

Tudhoe Grange, Spennymoor, Durham, Aug. 16th, 1884.

"British Consulate, Philadelphia, July 26th, 1884.

"SIR,—With reference to your letter of the 25th ult., I have to inform you that the University of Philadelphia is no longer in existence, its charter having been cancelled by the Government of Pennsylvania after a disgraceful existence of many years. Diplomas purporting to issue from such an institution are bogus and a fraud upon the community.

"Your obedient servant,

"ROBERT CHARLES CLIPPERTON,
Her Majesty's Consul.

"John C. O'Hanlan, Esq., M.D.,
Tudhoe Grange, Spennymoor, Durham."

RUPTURE OF THE COVERINGS OF AN INGUINAL HERNIA.

To the Editor of THE LANCET.

SIR,—I read with much interest in your last number the report of the case of rupture of the coverings of an inguinal hernia through the cicatrix of an old operation wound. In a similar case which I brought before the Medical Society last year, and which was reported at length in THE LANCET, the rupture occurred not through the cicatrix of the old operation wound, but through the sound skin, where it joined the cicatrix, and I should imagine this to be the most likely place for such a rupture to occur. I trust that in Mr. Keetley's case the statement made by the man of his treatment before reaching the hospital is not quite correct—viz., that "he walked a quarter of a mile to see a surgeon, who wrapped a piece of lint round the part, and ordered him to go off to a hospital at once; on leaving the surgery he walked back to the place where he left his waggon, and then took a cab to the hospital." Surely, no human being, still less a surgeon, would leave a man under such circumstances to shift for himself.

I am, Sir, yours truly,

Harley-street, Aug. 19th, 1884. BERNARD PITTS.

BIRMINGHAM.

(From our own Correspondent.)

CHOLERA SCARES.

CONSIDERABLE excitement was created in Birmingham on Tuesday by the prominence given by the press to the report that a death had occurred from Asiatic cholera. Careful inquiry, however, leads to the belief that an error has been committed in supposing this to be the case. The patient was a man aged forty-seven, living in a densely populated part of the town; the seizure took place about midnight on the preceding Friday, the man having gone to bed in apparently good health. The next day he was able to be downstairs and about the house, but became worse in the evening from diarrhœa, stomachic pains, and cramp in various parts of the body. He was better again on the Monday, but on a return of the symptoms died from collapse at six o'clock in the evening, after an illness of fifty-six hours. An official examination, under the direction of the medical officer of health, has shown the case to have been one of severe diarrhœa and collapse. The prevalence of diarrhœa in the town at the present time is very great. From the 10th to the 17th inst. 800 cases were treated at the General Hospital, and in one week at the Owens Hospital 490. In this instance the certificate of the medical man in attendance was filled up as "cholera" and "collapse." In the present state of public excitement on the question, it is incumbent upon medical practitioners to promote the confidence of the public, rather than to add to the apprehension which so many people have of this dread scourge. Judicious dealing with certificates of death, and careful comparison of known facts relative to the two diseases, will generally serve to distinguish between the true form of cholera and the more common cases of acute diarrhœa with collapse and cramps which occur in such frequency at this season of the year in all large towns. In the present case much needless alarm has been caused, which it is to be hoped will be assuaged by the prudent and clear letter which the Mayor has written to the public papers on the question.

IRREGULARITY IN DEATH CERTIFICATES.

A case of much public importance was heard at the Birmingham Police-court on the 15th inst., upon a summons taken out by the Superintendent Registrar against a Mr. Williamson, a local medical practitioner, for giving a medical certificate of the cause of death of a child he had not seen or attended during illness. From the evidence it was shown that the child was attended by an unqualified assistant of the defendant's, the latter signing the certificate after the death of the child. Some contradictory evidence was given as to the genuineness of the certificate, but the magistrates considered the case proved, and imposed a mitigated penalty of £5 and costs or twenty-eight days imprisonment. It cannot be too widely known that such offences are punishable in a greater degree than this, for if proceeded against by indictment, a conviction renders the offender liable to two years' imprisonment with hard labour, or seven years' penal servitude. Irregularities of this kind open the door to serious abuses of many kinds, and it is to the interest of the profession, as well as to the security of the public, that they should be protected from frauds of a similar character to this.

IRELAND.

(From our own Correspondent.)

ROYAL COMMISSION ON IRISH PRISONS.

THE Commissioners appointed to inquire into the administration, discipline, and condition of prisons in Ireland, both local and convict, report that they have inspected carefully the convict prisons, the majority of the local prisons, and some bridewells. At these visits an examination was made as regards the general structure of the buildings, the wards, cells, stores, and hospitals; also, the sanitary and culinary arrangements, the provision for the supply of water, and that for exercise and labour. Many of the

Digitized by Google

prisons were devised for an obsolete system of discipline, and therefore fall short of the requirements of the present day; only five may be regarded as coming up to the standard of modern construction; while of the remainder, twenty-two have been more or less improved, and eleven are unsatisfactory as regards construction. Before the passing of the General Prisons (Ireland) Act, 1877, the administration of the Irish Convict Prisons was entirely separated from that of the county and borough gaols and bridewells. The former were administered by directors appointed by the Lord-Lieutenant; while, on the other hand, the county and borough gaols and bridewells were under the direct management of local boards of superintendence. The General Prisons (Ireland) Act, 1877, transferred to a General Prisons Board all the county and borough gaols and bridewells, together with all the powers and duties of the local boards of superintendence. The Commissioners report that, from inquiries made, they do not believe that the Irish local prison system is administered with any intentional or systematic harshness towards the inmates. Where an excessive number of punishments appear to have been inflicted, they were cases of refractory prisoners whose mental condition may be described as the borderland between sanity and insanity, and where the application of penal discipline is confessedly difficult. They, however, are not satisfied that the discipline in all the local prisons is as regular and efficient as it ought to be, or that the means exist in them for effectively promoting the reformation of criminals; and are convinced that the fact of there being a large number of local prisons in Ireland, and consequently a small number of persons in most of them, lies at the root of the principal defects of the existing administration. No argument is needed to show that a superfluity of diminutive establishments must be as conducive to waste in expenditure as it is prejudicial to uniformity and economy of administration, and therefore the Commissioners are unanimous in opinion as to the superiority of larger over small prisons, and suggest that the prisons should be consolidated as to ensure, if possible, that the daily average population should in no case be less than one hundred.

THE DUBLIN TRIALS.

Before Baron Dowse, on Tuesday last, at the Court-house, Green-street, Dublin, James Ellis French was arraigned for a felony committed in May, 1883, and a jury was empanelled to try whether the prisoner was in a fit condition to plead guilty or not. Dr. Gordon, surgeon to the Constabulary, Dr. Eames, resident medical superintendent to the Cork District Lunatic Asylum, Dr. Curtis, a well known surgeon of Cork, Mr. Wheeler of Dublin, and others, gave evidence to the effect that Mr. French was not in a mental condition to plead to the indictment and conduct his own defence with due caution. On the other hand, Drs. Banks and Cruise, with Mr. McDonnell, were equally unanimous that he was unimpaired and in the possession of his faculties. There was no result when the electric battery was applied to the lower extremities; he had also a dragging in one of his legs, hesitation in his speech, occasional difficulty of deglutition, alleged loss of memory, &c. From the symptoms it was evident to Baron Dowse that Mr. French was suffering from some kind of paralysis, but from Mr. McDonnell's evidence it would appear that he considered there was nothing the matter with him mentally or physically, and that he would pass him for an insurance company, even if he were the doctor for that company; but his lordship added that he had a suspicion that if he did so, it would be the last man that he would ever pass for that company. In a conflict of medical evidence such as this the jury very naturally disagreed. It is possible that Mr. French may be suffering from locomotor ataxy, accompanied by nervous debility, but the case no doubt is an exceedingly complex and difficult one. The only specialist examined in the case was Dr. Eames of Cork, who was of opinion that the prisoner was not capable of pleading.

From reports of the condition of the Bishop of Limerick, who a few evenings ago ruptured a bloodvessel in his side, we learn that his lordship is making favourable progress towards recovery. He has been visited by his medical attendant, Dr. Vachell, who found his lordship's strength so far improved as to permit him to leave his bed for a short time.

PARIS.

(From our Paris Correspondent.)

FRENCH HEALTH-RESORTS.

I HAVE just returned from a rambling tour of about four weeks in the South of France, and I desire to send you a few general observations on some of the health-resorts I have visited *en route*; but your remarks anent the "health resorts at home," which lately appeared in THE LANCET, are so forcibly true that they have had a deterring effect on my mind, and I had almost given up the idea of troubling you, as what I have to say is simply corroborative of all you stated respecting the relative merits of the home and continental health-resorts.

France is certainly the most favoured country in the world as regards the number and variety of its natural mineral waters, but the conclusion I have come to from what I have personally witnessed is that the therapeutic value of these waters has been greatly exaggerated. Change of climate, change of scene, and change in the mode of living are doubtless important elements in the cure of chronic cases, which are at all curable, that are sent to the different watering-places. Those in France are the more generally resorted to from all parts of the world, as the French have the innate faculty of combining the agreeable with the useful, and they spare no expense or pains to render their health-resorts more attractive than is possible in any part of the United Kingdom. "Variety is charming," and there is no doubt that this is the great secret of the beneficial results obtained by travelling on the Continent or elsewhere away from home. Moreover, those who can afford the time and money will continue their excursions, in spite of all that may be said or written against their doing so, because it is fashionable for people to go away for a change at certain seasons of the year. For my part, excepting the notoriously insanitary condition of the dwellings, I was most favourably impressed with the general aspect of the country, and would willingly concede to it the epithet of "La belle France" given to it by its own inhabitants. After a few short excursions in the Basses Alpes I made my way to Aix-les-Bains, where I met with the most cordial reception among the medical staff, who, I was told, practised there in the most perfect harmony—a compliment that cannot be unreservedly paid to the profession in many other places in or out of France. Aix-les-Bains is certainly one of the most important thermal stations in France, not only on account of the curative properties of its waters, but because of the beauty of the town itself, which is situated at the foot of a range of mountains in Savoy, on the line of intersection between France, Switzerland, and Italy. Its altitude is 768 feet. It forms also the centre of the most pleasant excursions, an account of which is given briefly in a work "Guide aux Villes d'Eaux," lately published by Dr. Macé, one of the principal physicians of the place. The waters, which are thermal, and which are used for drinking and for douching, are partly alkaline and partly sulphurous, with a certain proportion of alum. They are said to be well suited for all cases of rheumatism, gout, and certain diseases of the skin, which, with the two former affections, are comprised under the head of "arthritism," whatever that may be. They are also useful in affections of the throat and bronchial tubes connected with gout and rheumatism, and in the various manifestations of scrofula and syphilis. The bathing establishment is one of the most complete to be seen anywhere, for besides the apparatus for hydrotherapy in all its forms, there are rooms fitted up with spray-producers, inhalers, swimming baths, &c., on a large scale. But the most important feature of the work of the establishment is "massage," which is here carried out to perfection, and renders immense service to those suffering from affections of the joints from whatever cause, paralysis, neuralgia, &c. According to the local physicians, the waters are, however, contra-indicated in phthisis, apoplectic tendencies, and heart affections. From a social point of view, Aix-les-Bains is provided with everything that could be devised to render the sojourn of visitors as pleasant as possible. The atmo-

Digitized by Google

sphere here struck me as being suited to patients suffering from lung affections, but I was told it was considered too relaxing in July and August, the height of the season, and this accounts for the place being frequented by English visitors only at the commencement and at the end of the season, which lasts from the beginning of May to the end of September, on their way to or from the south. There are two casinos (one too many, in my opinion), but I am not sure whether these would contribute much to the cure of patients who are induced to keep late hours and frequent heated rooms, and thus lose at night what they have gained in the day in the way of health and strength. This reproach may be applied to all the other watering-places. The cholera scare has proved singularly inimical to the interests of Aix-les-Bains, as it was reported that the disease was raging at Aix, which is in Provence, and this was confounded with Aix-les-Bains, which is in Savoy, where not a single case was known to have occurred. But, as might be expected, all the watering-places in France have suffered more or less from the same cause. Within a few minutes' drive from Aix-les-Bains is Marlioz, which may be considered a branch establishment of the former. The composition of its waters, which are cold, is, like those of Aix-les-Bains, partly alkaline and partly sulphurous, and, in addition, they contain iodide and bromide of potassium, which render them useful in catarrhal affections, scrofula, affections of the vocal organs, and the manifestations of syphilis in all its stages, particularly in the tertiary form of the disease. Like those of Aix-les-Bains, the waters of Marlioz are contra-indicated in the advanced stages of pulmonary phthisis. In my next I shall give an account of my visit to Royat, Mont-Dore, La Bourboule, and Vichy.

THE CHOLERA EPIDEMIC.

There is nothing particular to relate respecting the cholera epidemic which is still hanging about Marseilles and Toulon with varying intensity. It has, however, a tendency to spread to the neighbouring provinces, and has already made its appearance in the departments of the Aude, Ardèche, Vaucluse, and Hérault, where several fatal cases have been reported. It is also extending to the Pyrenées Orientales, where, at Perpignan and in the surrounding villages several deaths have occurred. In short, nearly the whole of the littoral of the Mediterranean is affected by the disease, and even Montpellier, which has hitherto escaped, has been brought under its influence, and according to a despatch just received there were reported on the morning of the 17th inst. six deaths as having occurred in that city. The disease seems to have a tendency to extend northwards. Paris, however, still keeps free and healthy. At Puits-le-Bon, a small village in the department of the Yonne, there have been fourteen cases in all since the outbreak of the epidemic, of which seven died. It is remarked that, on official inquiry, it has been ascertained that none of the persons affected had been in communication with the emigrants from the infected parts. There has been rather an aggravation of the reigning epidemic at Marseilles and Toulon within the last few days, the fugitives returning to these places being the principal victims. In sixteen hours there were two deaths from the disease at Toulon, and fourteen at Marseilles in twenty-four hours. Dr. Fauvel, unwilling to admit that he was in error as to his diagnosis of the present epidemic in the south of France, preferred sending in his resignation as Inspector-General of the Sanitary Service throughout the French territory, which has been accepted, and he has been replaced by Dr. Grousat.

DEATH OF DR. BURQ.

Dr. Burq, who became famous in connexion with metallotherapy, of which he may be considered the founder, and whose theories as to the efficacy of copper as a preventive and cure for cholera obtained a wide circulation, has just died at Bièvres, in the sixty-third year of his age. Whatever may be the opinion of the profession respecting the peculiar ideas of the deceased as to the action of metals on the economy, no one could contest his good faith and disinterestedness.

Paris, Aug. 19th.

THE BRIGHTON SEWERAGE.—A Local Government inquiry was held on the 8th inst. concerning an application by the Town Council for permission to borrow £25,000, for sewerage works. There was very little opposition, the question of high rating only being raised.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen have recently passed the Second Professional Examination of this College:—

Samuel Boake, James H. Bogan, Patrick Bolger, Louis Bagry, J. Casey, Edward A. Cooke, William Cotahan, Thomas Considlan, T. H. Corbet, Edward Corcoran, R. H. Cox, W. B. Dick, E. J. Dore, St. Leger John Edmundson, V. E. Fenton, Thomas M. Frood, M. J. Geary, T. A. Goodchild, John Hall, John W. Haughton, R. Hugo, E. Jacob, S. Long, H. Mathews, P. McDermott, J. B. Moore, J. E. Nally, S. H. Newland, J. O'Brien, J. O'Connor, F. G. Donohoe, D. O'Loughlin, R. D. Pennefather, R. M. Power, P. H. Power, F. J. Reid, M. Riordan, W. Ross, T. S. Sillis, W. T. Steele, E. Stoker, T. H. Strangman, W. J. Taylor, P. Tennaw, John Toppin, D. W. Turpin, Thomas Williams, T. H. Wilson, W. Woodright, C. S. Woodwright, E. Yates.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 14th:—

Hutt, Frank Charles, St. Margarets, Richmond.
Gemmell, John Edward, Queen-street, Waterloo, Liverpool.
Hughes, Samuel, Prince's-road, Liverpool.
Kendall, Henry Wm. Martindale, Renfrew, Bexley-heath.
Priestly, Robert Chambers, Hertford-street, Mayfair.

SIR CHARLES DILKE early in the week paid an official visit of inspection to the small-pox camp and small-pox ships and wharves of the Metropolitan Asylums Board.

THE salary of Mr. C. Gross, F.R.C.S.Eng., the medical superintendent of St. Saviour's Infirmary, Newington, has been increased from £400 to £500 per annum.

THE CANAL BOATS ACT.—It is stated that Sir C. Dilke has decided to appoint Mr. J. Brydone of Edinburgh, and late of Droitwich, to the canal boats inspectorship, under the Act of last session.

FOR the second time within two years Madame Patti, on the 14th inst., gave a grand morning concert in aid of the Swansea Hospital. The receipts amounted to considerably over £1000.

DEATH FROM SWALLOWING GLASS.—A boy recently died at Beckenham from spasm of the glottis, caused by swallowing some glass, a considerable quantity of which was present in a pot of marmalade of which the deceased had partaken.

MULTIPLE BIRTHS.—A woman at Bradpole, Dorset, recently gave birth to three boys; and on the 16th inst. the wife of a labourer at the Carlisle gasworks gave birth to four daughters. The infants in each case are reported to be doing well.

SINGULAR DEATH.—A boy who was recently bathing in the river Medlock, in Manchester, got out of his depth and swallowed some of the water, which was particularly filthy. Though immediately rescued by another lad he expired shortly afterwards, death, it is stated, resulting not from drowning but from poisoning.

ON the 14th inst., whilst Dr. Richardson, of Rhayader, Radnor, was returning home from a professional visit, his horse took fright and ran away, throwing him out of his conveyance and breaking his neck. Deceased, who was sixty-three years of age, had practised in Rhayader for many years.

THE Local Government Board have reversed the decision of the auditor by which nine members of the Milton-next-Sittingbourne Rural Sanitary Authority were surcharged in the sum of £32 odd, being the amount of a certain allowance or abatement, on account of water-supply, they by resolution made to a firm who owned all the cottages in the parish of Murston.

THE STATE OF THE RIVER WEY.—Much excitement has been aroused at Guildford by the fouling of the river Wey and the poisoning of the whole of the fish for miles along its course. The mischief is supposed to have been caused by the refuse from some manufactories on the banks of the river having been allowed to enter the stream. The Guildford Town Council is doubtful how far it can exercise its powers in the matter, but the inhabitants are getting up a petition to the Local Government Board, asking that authority to step in and remedy the existing disgraceful and dangerous state of things.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

ALDRED, JOHN CHARLES, L.R.C.P.I., L.F.P.S.Glasg., has been appointed Medical Officer to the Fourth District of the Ecclesall Bierlow Union, vice McBeath, resigned.

BENTHALL, WINFRED, M.B. Camb., M.R.C.S., has been appointed Honorary Physician to the Derbyshire General Infirmary.

CARTER, THOMAS EDWARD, M.B.Lond., M.R.C.S., has been appointed Medical Officer to the Stamford District and Workhouse of the Stamford Union.

COLLINS, E. TREACHER, M.R.C.S., L.R.C.P.Lond., L.S.A.Lond., has been appointed House-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

GREAVES, CHAS. AUGUSTUS, M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Honorary Physician to the Derbyshire General Infirmary.

GREENSILL, EDW. SAMUEL, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Witley District of the Martley Union.

GREENSILL, JOHN NICHOLAS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Martley District of the Martley Union.

HALL, THOMAS LAMBERT, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Dilwyn District of the Weobley Union.

JAMIESON, CHARLES, M.B., C.M.Glasg., has been appointed Medical Officer to the Fourth District of the Braintree Union.

JONES, EVAN, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Western District of the Llandilofawr Union.

KNOX, DAVID NELSON, M.B., C.M., F.F.P.S.Glasg., has been appointed Surgeon to the Glasgow Royal Infirmary.

PRINGLE, J. J., M.B., M.R.C.P., has been appointed Assistant-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice G. F. Coxwell, B.A., M.B., resigned.

TURNER, JOHN KEMP, M.B., M.Ch.Aberd., has been appointed Medical Officer to the First District, St. Columb, of the Major Union, vice Fulford, resigned.

WITCHELL, EDWIN AUBREY, M.B., C.M.Univ. Ed., has been appointed House-Surgeon to the Stroud General Hospital.

Births, Marriages, and Deaths.

BIRTHS.

ADAM.—On the 19th inst., at Malling-place, West Malling, Kent, the wife of James Adam, M.D., of a son.

GRANGE.—On the 6th inst., at Mansfield House, Moffat, N.B., the wife of W. D'Oyly Grange, M.D., of a son.

HARE.—On the 1st inst., at Woolwich, the wife of Surgeon-Major George Hare, Army Medical Department, of a son.

HOBSON.—On the 15th inst., at Lower Addiscombe-road, Croydon, the wife of John Morrison Hobson, M.D., of a daughter.

LITHGOW.—On the 14th inst., at Stirling House, Farnborough, Hants, the wife of Dr. T. G. Lithgow, L.R.C.P.Lond., of a son.

SCORESBY-JACKSON.—On the 12th inst., at St. Hilda's, Walthamstow, the wife of Thomas Scoresby-Jackson, M.D., prematurely, of a son (stillborn).

MARRIAGES.

HOLBERTON—TWINING.—On the 11th inst., at the Parish Church, Ballinakill, Henry Nelson Holberton, M.R.C.S. and L.R.C.P., of East Mouisey, Surrey, to Julia, fourth daughter of Frederick Twining, Esq., of Gleggan Tower, co. Galway.

RIGDEN—LOVELESS.—On the 12th inst., at St. Nicholas' Church, Brighton, Brian Rigden, M.R.C.S., of Canterbury, to Kate, younger daughter of the late W. Kerr Loveless, M.R.C.S., of Stockbridge, Hants, and Holly Bank, Southsea.

ROSS—WALLIS.—On the 13th inst., at St. Mary's Church, Southampton, Rhey Fairfax Ross, M.D. &c., son of J. Grafton Ross, Esq., of Sydney, to Edith Margaret, second daughter of Thomas Wallis, Esq., of Southampton.

DEATHS.

CUOLAHAN.—On the 20th inst., at 9, Grange-road, Bermondsey, S.E., very suddenly, Hugh Cuolahan, M.D., to the inexpressible grief of his wife and children.

DANIEL.—On the 14th inst., at his residence, Ramsgate, James Stock Daniel, F.R.C.S., aged 80.

JENKINS.—On the 31st ult., at Hawley, Hants, Robert Walker Jenkins, M.R.C.S.Eng., L.S.A.Lond., Medical Officer of Health, New Forest Rural District, formerly of 22, Philpot-lane and 13, Charlotte-street, Bedford-square, London, aged 54. Friends will please accept this (the only) intimation. (Delayed in transmission.)

KEMPTHORNE.—On the 18th inst., John Kempthorne, F.R.C.S., of Callington, Cornwall, aged 62.

LATHAM.—On the 15th inst., at Sandwell House, West Bromwich, Gladys Beverley, only child of George Latham, L.R.C.P., aged 10 months.

MCCULLOUGH.—On the 13th inst., at Wimpole-street, David Moore McCullough, M.D., late Medical Superintendent, Joint Counties Asylum, Abergavenny.

RICHARDSON.—On the 13th inst., through a carriage accident, Richard Richardson, Surgeon, of Bryngwy, Rhayader, Radnorshire, aged 54.

SCRASE.—On the 15th inst., at Lewes, Sussex, George Scrase, M.R.C.S., in his 81st year.

STEEL.—On the 16th inst., at his residence, Southfield, Lewisham, Charles Wilson Steel, M.R.C.S., L.S.A.Lond., aged 73.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

SANITATION AT HYÈRES.

DR. DUBRANDY writes to contradict the reports which have recently been circulated regarding the sanitary state of Hyères. Notwithstanding its proximity to Toulon, and the hospitality shown to the fugitives from that ill-fated town, the cholera has, he states, obtained no foothold in Hyères; and the deaths during the first seven months of this year have been less than in the corresponding periods since 1881, in which year they amounted to 203. In 1882 they were 210; in 1883, 222; and in 1884, 199. From January to the end of July in 1883 there were 231 admissions and 59 deaths at the hospital; in the corresponding period of 1884 the admissions were 184 and the deaths 31. Dr. Dubrandy attributes this happy result not only to the efficient system of sanitation which prevails in the place, but also to the admirable situation of the town.

Mr. J. Percival Hunt.—Application to Professor Liveing of Cambridge will no doubt meet with a response.

"THE LONDON UNIVERSITY PRELIMINARY SCIENTIFIC EXAMINATION."

To the Editor of THE LANCET.

SIR,—All medical students should thank Dr. W. H. Stone for his outspoken letter, published in your last issue. Professor G. C. Foster and Professor Reinold have been teachers and examiners for a great many years. Remonstrances have from time to time been made during the period of their examinership, but without effect. It is well known that this Preliminary Scientific Examination has been the bugbear of students going up to the University of London for at least twenty years. Alterations have been made from time to time; but there is no getting away from the pedantry and want of common sense exhibited by the framers of the ques[illegible] this examination. What is the remedy? In the first pla[illegible] of Physicians and the College of Surgeons combin[illegible] to grant the degree of M.D., as suggested by Dr. [illegible] let all teachers who have not the good fortun[illegible] combine to dissuade all students from going u[illegible] University at all. I see no other way of avoiding the [illegible] misery annually inflicted. There is, I believe, a sort of fiction that the members of the Council revise and sanction the questions set for the examination. But how many of the members of the Council have passed the examination themselves, and would therefore be able to judge of the suitability of the questions propounded?

I am, Sir, yours truly,

Aug. 18th, 1884. A READER OF THE LANCET.

Enquirer.—It does not entitle the holder to be registered or to recover charges as a medical man; but he will not be interfered with for practising. He could not, of course, hold public appointments.

THE MEAN TEMPERATURE OF NEW SOUTH WALES.

NEW SOUTH WALES, lying between 29° and 37° of south latitude, is cooler than the corresponding part of Europe. The mean temperature of the southern parts of England is about 52°, and that of France, near Paris, about the same, increasing as one goes south to 58·5° at Marseilles. The mean temperatures in the colony, on the other hand, are: Kiandra, the coldest township, situated on a mountain, 45°; Cooma, on the high land, 52°; Queanbeyan, high land, 53°; Goulburn, high land, 55°; Armidale and New England district, 57°; Mossvale, 55°; Kurrajong, 55°; Orange, 55°. These towns are scattered along the high table-lands from south to north, and represent fairly the climate of a very considerable portion of the whole colony. Next to this in point of temperature is the strip of land between the ocean and the mountains, and which is affected by the cooling sea-breezes. Here there is a mean temperature ranging from 60° at Eden, the most southern port, to 68° at Grafton, one of the northern ports. Sydney, in latitude 34°, has a summer temperature only four degrees warmer than Paris, which is in latitude 49°. Now, the total difference for a degree in latitude is a degree in temperature; and, therefore, if Sydney were as much warmer than Paris as its latitude alone would lead us to expect, its temperature should be 74°—that is, 15° warmer than Paris, but it is only 4° warmer. This single example is enough to prove the comparative coolness of the coast districts of New South Wales. The investigations made during recent years show that the mean temperature of the whole colony, as derived from forty-five stations scattered over it, is 59·5°, three degrees lower than that of Sydney, or only one degree hotter than that of Paris. It may be mentioned that the highest shade temperature ever recorded in Sydney was 106·9°, and near Paris a temperature of 106°F has been recorded.

Hospital Student.—The list of prize winners at the various hospital schools will, in accordance with our custom, be published in our Student's Number, to be issued on Sept. 13th.

WOODEN HOSPITALS FOR INFECTIOUS CASES.

To the Editor of THE LANCET.

SIR,—I should consider it a favour if you could give me any information about temporary wooden hospitals for infectious cases. I am attending a case of small-pox (imported from Liverpool) at Bangor Isycoed, a village about three miles from here, and there is no hospital for infectious cases in Wrexham, the nearest town to send the patient to. Are there any small wooden buildings for three or four beds to be had on hire in London or Liverpool, as there is no place to send small-pox cases to if it should spread in the village; or are there any tents to be had on hire? I should be glad if you could give me the name of any firm to whom I could apply.

I am, Sir, yours truly,

Overton, Ruabon, Aug. 18th, 1884. J. T. GOBAT.

*** We do not believe that any such wooden hospitals are kept in readiness, and previous experience does not favour their erection in the face of an actual outbreak. Tents may be procured by purchase or some six or eight patients from Messrs. Piggott Bros., 59, Bishopsgate Without, E.C., but we believe they are not hired. Doecker huts may also be obtained, but these have to be sent from Denmark. Under the circumstances, a hospital marquee tent seems most applicable; but otherwise it will be well to trust to vaccination, and at once to commence the erection of a permanent hospital, which would in the future be in actual readiness to meet emergencies of this sort. Even for a tent, a site, means of drainage, nurses' accommodation, &c., must be provided, and at best the plan will be a makeshift.—ED. L.

Subscriber.—We think our correspondent has no redress, as he, at least tacitly, accepted the terms of the guardians.

BORACIC ACID IN CHOLERA.

To the Editor of THE LANCET.

SIR,—Dr. Pegruasson advocates in a French medical contemporary (*Lyon Méd.*, No. 31) the internal administration of boracic acid in Asiatic cholera. He appears to believe that a large dose of thirty grains, while it would not produce any toxæmic effects because of the absorption by the mucous membrane of the alimentary tract being retarded and prevented in the disease, would destroy the bacilli. Having in view Koch's latest researches, it would, I venture to think, seem a trifle out of date to entertain any such view, so far as our knowledge at present goes. According to the illustrious German *savant*, the amount of carbolic (and indeed any other) acid that would be efficacious in destroying his comma-shaped bacilli would, *cæteris paribus*, also kill the patient, if administered therapeutically. Mention may here be made, *en passant*, of the fact that boracic acid has been tried by our Indian medical officers; and the present writer is inclined to think that Dr Bonstead (Transactions of the Bombay Medical and Physical Society) was one of them. It may also be noted that in 1878 Dr. Butler published a paper in your columns treating on the same subject.

I am, Sir, yours truly,

London, Aug. 16th, 1884. JOHN C. LUCAS.

Digitized by Google

BEVERAGES IN METALLIC VESSELS.

AT the suggestion of Dr. Cyrus Edson, of the Health Department, says the *Boston Medical and Surgical Journal*, an ordinance has been passed forbidding the use of vessels made of brass, lead, copper, or other metallic substance, in the sale of beer, soda-water, syrups, and other beverages or flavouring materials, on account of the danger of the formation of compounds detrimental to health. An investigation into the character of the lining of the soda-water fountains of Brooklyn is at present being made by Health Commissioner Raymond.

THE IRISH BRANCH COUNCIL AND ERASURE OF NAMES.

To the Editor of THE LANCET.

SIR,—I very frequently receive a circular from the Irish Branch Medical Council, marked "Second application prior to erasure," inquiring if I had changed my address &c., never having received the previous application. I received a similar communication at the end of last September awaiting me on my return from Europe, where I had been absent for two months. This I immediately replied to, and yet before eight months had elapsed I got another, dated May 12th, 1884, threatening erasure if not answered.

It strikes me the Irish Branch Council is in a great hurry to erase names prematurely from the Register. If all its other duties are discharged with equal zeal and promptitude it is a most efficiently conducted office. The circular gives an extract from the Medical Act 21 and 22 Vict., which provides that it shall be lawful for the registrar to send a letter to any registered person which, if not answered within six months, the name of such person may be erased from the Register.

Now, such communications as I have invariably received from the registrar have been in the form of an open circular. I am not sufficiently versed in legal lore to decide what constitutes a letter, but this I do know, that if a sealed letter is addressed by a person in Great Britain to one in the United States it will be delivered, even though the postage has been insufficiently paid or not paid at all, and double postage collected on delivery, whereas a newspaper or other mail matter below the class of a letter, including circulars, if sufficient postage has not been paid, will not be delivered at all, which probably accounts for my non-receipt of the prior communications referred to.

It is a matter of small moment to me whether my name is erased or not, but there are doubtless others who, after an absence from Great Britain, may return to practise their profession there and find themselves debarred from doing so save at the cost of great inconvenience and worry, owing to a miserable official parsimony in the matter of a penny or two.

May 12th seems rather early in the year to send out a final application.

I am, Sir, yours respectfully,

Ashton, R. I. N. O'D. PARKS, L.K.Q.C.P., &c.

*** The publication of this letter has been unavoidably delayed.—ED. L.

"IS DEAFNESS A BARRIER TO PRACTICE?"

To the Editor of THE LANCET.

SIR,—My late father was in practice upwards of fifty years in one place, and brought up six children without any other aid. During this time he was deaf. These are the words of his sister-in-law to me: "Your father never seemed to be at any loss with his patients." I hope his case may prove of some comfort in that of a "Constant Reader."

I am, Sir, yours faithfully,

Kennington-park-road, Aug. 17th, 1884. C. CORBETT BLADES.

To the Editor of THE LANCET.

SIR,—Allow me to suggest to your correspondent "Constant Reader" the advisability of learning "lip reading." Aided by developed seeing-power, he would undoubtedly be able to carry on his practice; and I shall be glad to make an appointment with him to explain the system, and to show its practicability.—I am, Sir, yours truly,

WILLIAM VAN PRAAGH.

School and Training College for Teachers of the Association for the Oral Instruction of the Deaf and Dumb, 11, Fitzroy-square, W., Aug. 19th, 1884.

Mac.—An application for a fee of, say, £2 2s., accompanied by a letter explanatory of the delicacy of the operation, would probably meet with a satisfactory response from the guardians. We should be glad to be informed of the result.

"PREVENTION OF 'HARVEST BUMPS.'"

To the Editor of THE LANCET.

SIR,—Pardon my asking if you think that the letter signed "C. S. Taylor," on the above-named subject, was seriously meant, or whether it was not sent by mistake to you instead of to the Editor of *Punch*? Does the writer believe that a family going for a holiday to the seaside would be provided with all the means and appliances that are suggested therein—means more troublesome than even the irritation of harvest bugs—the antidote worse than the bane—measures totally impracticable under the circumstances referred to?

From personal experience, I can say that carbolic soap is useless to prevent the bites. The suggestion of the use of quassia chips (by Mr. Penny) infused in the water used for ablution or baths has everything to recommend it. Sulphur is too offensive, and fumigations too elaborate for lodgers.

I am, Sir, your obedient servant,

Seaton, Devonshire, Aug. 19th, 1884. M.D.

Medicus.—Muscæ volitantes in a large number of cases arise from errors of refraction. Let "Medicus" have his refraction ascertained, and, if necessary, corrected, by a competent authority, and in process of time the muscæ will disappear. If this be not the cause, then the symptom may arise from disorder of the general health, which an intelligent medical friend will discover, and possibly remove.

Dr. Martin.—Next week.

TREATMENT OF SICK HEADACHE.

To the Editor of THE LANCET.

SIR,—There are few diseases of which the most careful outline of diagnosis, prognosis, &c., is not fully detailed in all our standard works, but I regret to say that the question of treatment is often dismissed as of little consequence. I think, therefore, it is worth while briefly to detail the following case, where the treatment was so marked in its success.

Mrs. N——, aged twenty-six, married, two children, had all her adult life suffered to some extent at the periods, and also was troubled with what is commonly called "sick headache." She was treated by various doctors in the Western States of America, and at length she sought the advice of Dr. Thomas of New York. He came to the conclusion that the only possible relief was to be obtained by removal of the ovaries; that she was then much too broken down for the operation; but after a trip to Europe had set up her health he would, on her return, operate. I first saw the patient in June, 1883. She was then in the second day of the period, and under one of her headaches. These begin in one side of the head, and the pain gradually increases until the patient loses consciousness; the limbs become rigid, the hands clenched, the eyes half open and turned up, and shivering fits come on every few minutes. At other times the attack takes the form of spasm of the glottis. Seeing her first in one of her severe attacks, I introduced my hypodermic needle, and injected one-sixth of a grain of morphine. I left the needle in, and in seven seconds relief was obtained; but as it was not complete, at the end of five minutes I gave the same quantity, and withdrew the needle. The pain subsided, and did not return during that period, but the patient suffered from severe sickness, which lasted thirty hours. In a few days I ordered iron and quinine, with shower-baths, good food, and early hours. When the next period was expected, I gave belladonna and bromide of potassium. As soon as the period came on, I kept the patient in bed, applied a blister of the size of half-a-crown over each ovary, and ordered a morphia pessary at night. The period passed over without a sign of pain or trouble. The tonic treatment was resumed, and the patient's health steadily improved. The next period was anticipated a day or two with the belladonna and bromide, and when the flow began, she was kept in bed the first day with half a mustard leaf over each ovary. No pain; period normal. On the next occasion, feeling the restraint irksome, and forgetting the date, the patient went to a theatre on the very night of the return of the period, and at 1 A.M. I was sent for. I injected one-third of a grain of morphia; the relief was instantaneous, and by increasing the dose to half a grain, the sickness diminished. I tried the addition of atropine, but without effect. By persistence in the treatment, essentially the hypodermic, the patient is freed from headache, and no longer looks sick in mind and sick in body, having regained colour in her cheeks. I have repeatedly seen the same good effect in ordinary sick headache, either from hypodermic injection of morphia or from a dose of chlorodyne.

I am, Sir, yours truly,

Gloucester-road, July, 1884. RICHARD G. JACK, L.K.Q.C.P.I., &c.

THE ILKESTONE "BATHS."

To the Editor of THE LANCET.

SIR,—In your account of home health resorts in THE LANCET of the 9th inst. you mention Ilkestone, near Nottingham. In order to prevent disappointment, I will relate my experience of this place.

Two years ago I spent my autumn vacation in examining some of the English spas, and, attracted by the description in Black's Guide to Derbyshire, I set apart a day to visit Ilkestone. On arriving at that very uninteresting town, I asked for the baths. After several persons had told me that there was nothing of the sort in the place, I was directed to a public-house, and, on inquiring at the bar, found that there had formerly been a bathing establishment attached to the house, but that the baths had been disused for nine or ten years!

I am, Sir, your obedient servant,

Queen Anne-street, Aug. 16th, 1884. F. DE HAVILLAND HALL.

Inquirer.—We do not prescribe. A medical practitioner should be consulted.

"METHOD OF TREATING SPRAINS."

To the Editor of THE LANCET.

SIR,—I am inclined to agree with Dr. Dinin that the efficacy of Mr. Shearer's method of treating sprains lies solely in the compression. The principle of firm, equable pressure is by no means new. For some years it has been practised by Professor Chiene of Edinburgh, who, as far as I know, was the originator of the method. Mr. Chiene's treatment consists in enveloping the parts in a very large quantity of cotton-wool, and then applying firmly an elastic bandage.

I am, Sir, yours obediently,

J. CHALMERS ROBERTSON, M.B., C.M.

Glenkillie, Blairgowrie, Aug. 19th, 1884.

A Sketch
OF THE
LIFE AND PROFESSIONAL CAREER
OF
CHARLES HILTON FAGGE.[1]

BY WALTER MOXON, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

VERY few years have elapsed since the honoured name of John Hilton had for all Guy's men the same melancholy interest as now surrounds the name of his nephew. Hilton's loss was deeply felt, though he died full of years and of well-merited honours. But there is bitter disappointment mingled with our sorrow as we see Fagge take his place in that dimmed light reflected off the face of each one as he finally recedes from the gaze of the men amongst whom he lived and worked. Those who knew Mr. Hilton will not think it out of the course of hereditary nature that another of the same stock should be born to acquire greatness. Indeed Hilton and Fagge were men whose excellence was due to their natural power; and although perhaps their family likeness was not evident at first sight, yet, in truth, it was for the most part the same kind of power that formed the foundation of character in each of these great healers of men. The robust figure and rather rallying address of Hilton might strike one as contrasting with the milder outlines and most unaggressively influential presence of Fagge. But those who knew Mr. Hilton learned to regard in him a refined delicacy of sentiment which was more upon the surface in Fagge. Whilst those who knew Fagge were aware of his most robust strength of resolution when circumstances gave occasion for determination of purpose. He was sensitive, but his sensitiveness was gentleness, not weakness. But in both men the ruling power that governed and controlled and directed alike themselves and all whom their influence prevailed with, was innate honesty and truthfulness—the power in which they lived and moved, and had their being. I say innate, because it seemed as if instinctively Hilton and Fagge always had a sure grasp of the reality and the practical significancy of truth and fact. The reason has its instincts, and it appears to me that some happy men are born with a natural power of ignoring irrelevant bearings in matters under inquiry. People talk as if instinct was always animal and reason always human, but there is human instinct as there is animal reason. True, the human race collectively elects to pride itself on reason, and would for the most part say little about human instinct. Perhaps this is because it has suffered much from the human instincts of its leaders, and under their influence has gone rather unreasonably and unsteadily. So that the world has learned to distrust instinct and to say always its good things in favour of reason, even when not following it. But the true human instinct is social goodness of aim; the identification of self with interests that are socially constructive, and positive, and real. This true type of manhood was embodied in Hilton and Fagge, and made them in the highest sense good men. Men in whose presence the faculty of imitation was a blessing and made a better man of you. Men devoted to faithful inquiry; free, yet always affirmative. It is so tawdry easy to be free and negative. But these men seemed incapable of mere negative questions. Well, call it incapacity if you will. Let it be a limit of vision which keeps some of the most clear-sighted of men from seeing the interest of those questions which in their negative results annul all that humanity is founded on; those questions by forcible aversion from which human society became possible. Perhaps it is partial blindness; but if it were not for the blindness in the backs of our heads, we probably should never have learned to go forward; and any human monstrosities with mental eyes all round, behind and before, need not be proud of such universality of view.

The limitation of the field of inquiry has been the cause of the greater productiveness of modern as compared with ancient philosophy. In modern philosophy we turn away from all questions that do not lead to beliefs, and thus we escape metaphysics. It is only by belief we are saved from metaphysics. It is sound sense and sound sense knowledge that saves us: knowledge always referable to and founded upon our five of six senses; communicable knowledge capable of becoming what we call common sense, which is the mutual use of their senses by a sufficient number of persons. Patience in direct observation of nature, seeing and measuring and weighing and recording, and so having true beliefs—beliefs founded on sense-knowledge of nature; such beliefs as are always mutually realisable, and therefore sure. Belief is, in the mind, the equivalent of sensuous realisation. It is the same thing to believe in the mind as to realise by sensation. Belief is the special sense of the higher intellect. It surpasses sensation, but is founded on it. When there is no belief beyond the evidence of the senses, it is as if the fire fails to glow out beyond the fuel and dies down amongst the embers. Yet belief must be in continuity with sensation, even if that continuity is as indirect as the laying on of hands in the Apostolic Succession. By faithful belief are we *still* saved. Saved from metaphysics, which is mental humanity floundering with eyes all round the back of its head. This philosophy, which I feebly try to express, began with Bacon, and led to the development of what we now call "science," which, as it has all its grounds directly in the senses, might be called "five-sense philosophy." Like all other human things, it is never safe when too confident, and even now might at any time come to a bad end and go off into the most rubbishy metaphysics—such as those shadowed in the latest phases of Comte or of Huxley. That is, if science were so weak as to follow the reactionary turn of its leaders when they grew tired of being five-sense sensible, and try to escape from the narrow limits of sense. For the limits of five-sense philosophy are so narrow that the end can be seen from the beginning. It is very curious that Bacon, in his "Novum Organum," should at once have proceeded on the assumption that forms, as he called them, are kinds of mechanical motion. (He meant by forms forces expressed in terms of laws.) The most advanced five-sense philosophy has got no further than this. And, in truth, our five senses are just five means of analysing, or revealing to us, the properties of motion. And every whim and dream in Bethlem Hospital, alike in the patients and in the physicians, is just an analysis or revelation of the nature of motion. And Bacon saw this in a foreshortened kind of way directly he looked as far as possible ahead along his new five-sense philosophy. I have called it an analysis or revelation, but, of course, you will see that these two are the reverse of each other. Analysis is the human mental progress from the special to the general. Revelation is the divine progression from the general to the special, in which line we enjoy just as much as God lets us; and we may just as well see it all very humbly. If God had given us two or three more senses we should have experienced just so much more of this analysis or revelation of the nature and properties of motion. Hilton and Fagge were instinctively observers. There was no possibility of rubbishy metaphysics about them. They recognised that the world of true and faithful inquiry is still, as always, bounded by a limbo of faithless questioning and faithless doubting—a limbo in which the luxury of doubting makes science as impossible as it makes religion. Science also has its duties of belief, of good faith, of trustworthy purpose; and those who revel in the ethereal joys of idealist and transcendental scepticism are by comparison with such men as Hilton and Fagge merely human flummery. Modern science is securely founded in the sense knowledge of nature. This knowledge is now brought in with ever-increasing enthusiasm. There is a solidarity about the system of its collection. The certainty and communicability of each result give to its discoverer a recognised distinction to reward him amongst his fellows. Each contributor gets credit for his contribution, even the smallest. This is of course extremely satisfactory, seeing that everything contributed is what is perhaps tautologically called "real fact"—tautologically unless facts are liable to be unreal, which in this inscrutable world may be really the case. And for evidence, I need not refer only to the S.P.G.S.—the Society for the Propagation of Ghost Stories. But it is as well to notice the weakness of a too enthusiastic pursuit of the sense-knowledge of nature. Five-sense philosophy has no right to suppose itself to have other grounds of per-

[1] This paper was written too late for its place in the Guy's Hosp. Reports.

Digitized by Google

sistence than those enjoyed by the five senses themselves; and we know that the five senses only maintain their place in the animal economy by reason of their constant and continued usefulness. When of no service they go. Why, then, should five-sense philosophy hope to maintain its place in the social economy on any other grounds than those of its continued usefulness? The eyes of creatures in a certain cave in Kentucky have disappeared wholesale. Bats that fly of a night have no eyes to speak of. It is true that owls that also fly of a night have wonderfully great eyes, which is a very remarkable and instructive fact. Taken with the natural history of bats it shows that when the amount of light which exists is insufficient there are two natural ways of dealing with the difficulty; one, like the bat, of giving it up altogether and losing the organ through which light is used, the other of doing the very best you can with what light there is, in which case you are rewarded with extra splendid organs of sight. In this way the owl acquired extremely powerful organs of vision, and was therefore made the type of wisdom, which again is a remarkable thing; because the owl got those wise-looking eyes by a habit of looking after its business in the dusk, whereas the twenty-four hours had always brought as much good daylight to owls as to other people, but the owl chose to be most active in the dusk, and so got great eyes and was taken as the type of wisdom. Whereas other birds remained less wise-looking because they kept active in full daylight, where they were not obliged to goggle their eyes after obscure things. And five-sense philosophy may acquire a reputation for wisdom on principles parallel with those which gave the owl great eyes, and may grow so clever in flying deeper and deeper into the dusk that in the daylight amongst ordinary birds it may be reduced to blinking and looking goggley. For social full daylight treats little questions, not by studying them as stars are studied in the dusk, but by drowning them and overwhelming them as stars are overwhelmed in the daylight. Five-sense philosophy, or science, as it is called, may be lost with bat's eyes, or be grown all a-goggle with owlish exaggeration of acuteness. Too great to fit it for the natural sunlit world in which men will always have their chief enjoyments, and therefore their chief interests, even though their relation to light be much like that of so many blue-bottles buzzing up and down a window pane, unable to perceive that the lightest way is not the best. If we carry inquiry after sense-knowledge into extremes that are out of relation to any natural social requirement, all excess of the kind will prove as flummery, as mere metaphysics. Sense-knowledge beyond what is serviceable is a luxury.

Any who are naturally led to indulge in the luxury of unrestrained inquiry owe more than they are apt to pay to those devoted minds who so use the tree of knowledge that it shall bring forth good fruit for our service. There is so much that is tempting in the vast range of medical study calculated to call men off in even the most praiseworthy spirit of search after sense-truth, as that sense has its thirst for exact results are drawn into exaggerated intricacies of physiology, and others in the charm of inexact results let us into watery glancing whirlpools of psychology with a chapter on the "Disintegration of the Ego." Others wander into social problems. Seeing how many are lured away by these temptations, should we not very highly appreciate those men who are enthusiastic and devoted, and nevertheless are so well balanced that they give their lives to their proper business of laboriously and faithfully following, and patiently studying, those most difficult and fugacious of all objective realities, clinical facts—transitory phases of complicated problems which so readily escape even the quickest eye, and are so difficult to record in the most tenacious memory. Herein was Fagge's special greatness. He was the physician by grace of nature. He was gifted with quickness and with patience in observation. He had a genius of the eye for clinical facts. It needs something almost creative in the eye of the observer who will gather the signification of the successive scattered appearances that make up a clinical fact. It is a high example of that power which, perhaps, is best illustrated by its likeness to what we have all seen in the twirling toy called a thaumatrope? the power which blends fragments and snatches of view into unity of form and vital continuity. We ordinary physicians owe more than a passing tribute to men of this rare power. The genius of the eye which makes an "observer" such as Sydenham and Addison, and in our day Hutchinson, was possessed in a high degree by Fagge. It is an admirable genius; it requires a quick seizure and a tenacious hold of things, whilst they are yet developing and not ripe for communication. Such as each man must know for himself, as perceptions which give him his special experience—things such as each man ought to keep to himself until they are worth communicating. Some would-be Sydenhams have a painful incontinence of these perceptions, sending them out in a hurry, as if they instinctively feel that they will not keep. But there are men who have a much more truthfully realising sight than others. They perceive more quickly what it is that they see, and they remember more tenaciously what it was that they perceived. It is a gift. You may develop your share of it, but you cannot draw yourself up higher in it than you were born to rise, and when you are, so to speak, on tiptoe, such men as Fagge are above you. But such men are rare. This genius of the special senses of eye or ear is a sign of good derivation. Fagge was of good derivation. He had good eyes and a portion of his brain acted instinctively with his eyes. This is another curious thing, and it is worth while to reflect upon it a little. In Fagge the optic lobes, which are the brain of the eyes, wherein resides the genius of sight, had not dwindled quite away. These good eyes and persistent optic lobes saved him—saved him from a danger which was especially perilous to him on account of his amazing power of quickly apprehending and tenaciously holding other people's views. If you can rapidly pick up other people's views you hardly want eyes. And Fagge's power of appropriating views was something almost incredible. It enabled him to perform that startlingly striking feat which at the London University is ever memorable. Lest his great feat of student learning should have been lost sight of in the greater lustre of his later career, I will shortly tell the story of it. When Fagge went up for his First M.B. at the London University there were three exhibitions and four gold medals as rewards for chief distinction in four widely different and large subjects—namely, anatomy, chemistry, materia medica, and botany. Now, Fagge took all these exhibitions and gold medals. Truly, never was an advanced educational embryo in greater danger. Wise men shook their heads, and said, "Ah! these prize-takers never do anything original." And the wise men were almost ready to pity the poor fellow, especially those wise men who had not themselves done quite so much at the First M.B.

It was with this evil presage that my late friend entered upon the real life in which the student and all that he did is soon lost sight of. And as I speak now in admiration of Fagge, I do believe the danger indicated by those wise men was a real danger. Indeed, other prize-takers who did nearly as much remain pitiable examples of the risk. The more thoughtfully you contemplate the circumstances the more real will the danger appear. It is not merely the danger lest the future life of the man should be of small excellence in comparison with the brilliance of first achievement. This danger is real in its way; it spoils the idea of a life when from a large foundation a low elevation is reached. A vast memory spreads a wide base for your edification, and if what you construct upon it goes no higher than that which your competitors raise on their narrower base, then, if I may so metaphorically speak, the proportion of broad base to low height in you makes a squat sort of pyramid of you; and your competitors with narrower base and equal height give the impression of sharper fellows. And so a short memory may even confer advantages on a reputation for sharpness, especially as shortness of memory is apt to first affect the knowledge your competitors have of where they got the little they happen to know. And Fagge had an immense memory, and in his student life spread a vast base for that constructive future, which is the proof of real value by which a life has to be estimated. His immense memory endangered his optic lobes lest he should disuse his own optic lobes and trust to views got at secondhand into his cerebrum from other people without putting his own eyes to any use or practising his own optic lobes. The optic lobe or brain of the eye, like many other good things, has a tendency to dwindle as you go on in life. It begins dwindling very early in you—in fact, almost before you are yourself at all. When your embryo is going through its very early periods in the fish stage, in the bird stage, and so on to the monkey stage, as it is gradually, in the fulness of time, to become a man-child, you—that is, your embryo—have very large optic lobes, corresponding to the great eye-brains which characterise fishes and birds, and so on. But in becoming human the optic lobes dwindle in you so that you cannot, as a human being, realise what sight is in the more perfect eyes—say, for instance, even in a robin, that can see the tail of a worm in the grass 30 ft. off, so that it can go straight off an apple tree to that tail with unerring sureness; or in a chicken,

Digitized by Google

that becomes familiar with the whole world as known to chickens in the first two weeks it gives after leaving its egg-shell and stretching its legs. The human sucking embryo stretches its legs and winks for whole months, and sees nothing at all with his miserable dwindled optic lobes and his jelly-looking eyes. The reason, of course, is, that the human baby is not so immediately dependent on his eyes as the chicken is that has at once to look about when to be hatched and pick up all it can for lack of mother's milk. The human mother's eyes do duty for those of her offspring. Hence the eyes and optic lobes of your embryo were allowed to dwindle immensely, whilst your cerebrum grew disproportionately great. As a man-child you begin life by thinking about what other people see, and your thinking machine or cerebrum becomes so much more active a thing that you may think a great deal in proportion to what you see all your life; in fact, your over-active big cerebrum may press down on your tentorium cerebelli, and so sit heavily upon and oppress and squash and quell the more vital parts beneath the tentorium; and the optic lobes are perhaps still worse off, having no tentorium to protect them from the pressure. Everything in nature is on compensation principles. Brains enough to make you stand upright weigh on the roots of your eyes when you are up. And just as your mother will see for you whilst you are a sucking embyro, so your teachers will see for you during your educational embyro stage. As a modern young man with any cerebrum to speak of, you need never use your own optic lobes—in fact, your eyes may almost be kept for mere ornament. Of course, this is not only true of vision, but of much else, so that your mother may supplement your little goodness by her greater goodness, until you shall have no opportunity of practising the little goodness of your own, and when you are left to yourself you may find your little stock of original goodness scarcely enough to keep your character decent when away from your mother's wing. And even when you are what is called adult, everybody all around you will supplement your imperfections, will see for you and hear for you, do anything for you for a very small return of flattery. That is the great advantage of social life in high states of civilisation; everybody will not only hear for you and see for you, but will tell you what you ought to think about it all. And so you may be completely civilised into a kind of Nirvana, and exist without the trouble of either seeing or hearing or thinking; and in this Nirvana you may gaze listlessly across at Schopenhauer and Hegel, express how divine an existence of the Epicurean gods it all becomes—nothing worthy of attention and nothing getting any, because other people do it all for the sake of some equivalent as trifling as the whole affair deserves. Into this Nirvana perfection of civilisation the modern young man can enter without ever having had to use his own eyes except as a kind of ornament on his very intellectual face, or to preserve his mental balance by recognising objects as he has been taught them, or to avoid knocking against inconvenient realities. And modern philosophy is, as we have seen, so thoroughly founded on the real and true, as seriously known, that the modern young man can afford to be tenatful. His teachers do really know, and he may accept their views. Why should he use his own eyes? Because see a little at a time, and with his dwindled and distrust optic lobes perceives so little of what he sees, that looking is a waste of time compared with the facility with which he can pick up other people's views and adopt them in his cerebrum, and say, "I know I see"; and so he says, "Yes, I see" without eyes looking. And he does not move your pity like the poor man blind from his birth who rolls his chalky wasted eyeballs and speaks of sight when of its saddest want he is for the moment oblivious as he says, "I see," in happy delusion that eyesight is his. The modern civilised Nirvana young man, speaking of his views and saying "I see," does not move your pity, though he never did see anything of the fact of the matter any more than if he were blind from his birth. His sad privation is not so touching. You cannot see his poor, wasted, atrophied optic lobes, and his eyes appear all right to look at.

But Fagge was no mere collector of other people's views. He was of good derivation, and had persistent optic lobes. He was a seer; he was no mere cyclopedia with a self-acting index edited on the principle that knowledge is power. His gift of sight brought his large knowledge to bear; there was the man with all his knowledge. But knowledge be power if you will, but another character is wanted to determine the effect of it. The Assyrians seem to have perceived this, and to have inscribed it in a symbolic way at the doors of their palaces, putting the body of a bull or a lion to the head of a man—hinting that if you know like a man you must be ready to act like a bull or lion if you are going to live in a palace. The Assyrian man-headed bull was not far wrong. It was more right than the griffin coat of arms of the Middle Ages, which left the man out altogether; but they were scarcely human then. Knowledge is not power. The relation of knowledge to power, like all high truth, can only be expressed in symbols; but at least one may say that the head full of knowledge needs a character which shall determine its use. The greater the knowledge, the more powerful must be the character; and Fagge was a great physician because, with his immense knowledge, he had the character of a physician. Our modern governments by the lower middle class, the industrial and positive class, who are able to know positively all that can be known positively, and who do not care for symbols nor for whatever can only be expressed in symbols—this lower middle class government has determined that knowledge is power; and, as the nation must be powerful, it compels everybody to know, and fits them with knowledge, as it were with firearms or dynamite. In the lower middle class of great communities knowledge is everything; the vast web of human knowledge surrounds you and occupies the whole horizon, like the brick buildings of the vast community which nearly everywhere shut out the sky. Each man's knowledge is so small and fragmentary that he must for his hold on existence look around to his fellow men whose vast knowledge can supplement his few trifles. He need no longer look up to God, as they used to do when human knowledge had not occupied all the heavens and the earth with five sense certainties. And so the lower middle class, our masters, entirely believe that knowledge is power, and the logic is something thus: Whoever can be taught can know; and whoever can know can do, because knowledge is power; and what care we for intellectual considerations—for instance, whether a beard comes on the face of knowledge. Let us ask of the beard "Whence art thou?" And as it retires abashed, let us treat the widest knowledge as the greatest power. *Hic itur ad astra.* Celestial! Did not the Chinese learn to award all positions of power in virtue of knowledge and success at examinations, and did not they soon find and call themselves celestial? They managed the natural tendency of females to excel in mere knowledge better than we do. They persuaded the sweet creatures that it was the right thing to have their feet pinched, and this drew attention to the other extremity. We have not yet found anything so effectual, but there is time. The Chinese celestial civilisation is much older than ours, and it may have taken centuries to induce the ladies to choose pinching their feet as the correct competition for female excellence.

That knowledge is power is a feminine truth; it belongs to the side of nature that receives impressions. Fagge was no mere receiver of knowledge. He was a man of very great character—of very great medical character. True, great medicine is never grand. It would be absurd in the House of Lords. I know no argument for putting physicians in the House of Peers, unless it be to apply astringents to the eyes of the last conspicuous addition to the Upper House. In the House of Lords, as in the Celestial City, tears shall be wiped away from all eyes. Can you imagine a British noble ever weeping at so much a volume? No; astringents are wanted: a sponge—a big sponge—and to hold it, a big hand, even if a "big merciless hand." But Lord Tennyson himself shall describe it—

BALLADS AND OTHER POEMS, PUBLISHED DECEMBER, 1880

IN THE CHILDREN'S HOSPITAL—EIGHT.

"Our doctor had called in another, I never had seen him before,
But he sent a chill to my heart when I saw him come in at the door;
From from the surgery—schools of France and of other lands,
Harsh red hair, big voice, big chest, big merciless hands.
Wonderful cures he had done; O, yes; but they said too of him
He was happier using the knife than in trying to save the limb.
And that I can well believe, for he looked so coarse and so red,
I could think he was one of those who would break their jests on the dead.
And maybe the living dog that had loved him and fawned at his knee,
Drenched with the hellish Oorali—that ever such things should be!

* * * * * * *

And he said to me roughly, 'The lad will need little more of your care;'
'All the more need,' I told him, 'to seek the Lord Jesus in prayer.
They are all His children here, and I pray for them all as my own.'
But he turned to me: "Ay, good woman, can prayer set a broken bone?"
Then he muttered half to himself, but I know that I heard him say,
'All very well, but the good Lord Jesus has had His day.'"

And is it thus that great medicine is spoken of in the House of Peers? No, peers speak and write like gentlemen. Scorn seeking scorn to scorn seems the speciality of poets. How came he to be there? Is the House of Lords the seat of the scorner? Ah! that insidious Gladstone! What could he mean by imposing the author of those scurrilous lines on the much-threatened Upper House. A few more such additions, and—— The only just all-round atonement Lord Tennyson could make would be to give the pecuniary proceeds of "In Memoriam" to that hospital which he had in mind when he penned those unspeakable lines. Was it the Evelina Hospital for Sick Children? Dr. Fagge was physician to that hospital. The amends might be made in his honour. But the subject is quite unworthy of Fagge. Fagge's greatness as a physician appeared in his always kind and sympathetic and Christian treatment of the sick poor. It is easy for poets to put their own denials of Christ into other people's mouths, and then as fashionable authors to spread them about on drawing-room tables. It is convenient to be able to work off your baser sentiments in a false character; you yourself then appear pure by contrast with your own creations. But if one's solemn everyday duty is spent face to face and eye to eye with the sorrowful and suffering poor, one wonders how even a poet laureate could be capable of thinking the matter of those loathsome lines of this new peer. I wonder is he yet ashamed of them? What footing has this poet aristocrat on any grounds of charity that justifies him in putting his blasphemous sentences into the mouth of the child he supposes? Let him go into a children's hospital, and see how far the poor sick little ones think as vilely as he of the kind-hearted doctor whose only sorrow is that his best help to his little patients too often proves ineffectual. Fagge was physician to the Evelina Hospital for Sick Children. His sympathies were not with grandeur and the House of Lords. He worked for the suffering poor, and his sympathies were with the poor. And remember it is always more difficult to get the sympathies of the poor. They are poor mainly because they do not sympathise with much that their betters enjoy. It would be a slight to medicine to suppose that this makes them, from the doctor's point of view, more easy to sympathise with. Nay, are not the poor used as the practising ground for extra strong sympathies? But, indeed, just as the Jesuits succeeded splendidly in education through perceiving that the lowest pupil wanted the best teacher, so, if you will condescend to know the truth, you must know that to succeed with the poor needs the best doctor—the most medical doctor. Fagge was, to my mind, the type of true medical greatness. Perhaps he might have been corrupted into grandeur if his life had been spared. There comes a danger of that kind of corruption after forty or forty-five, even in the greatest of truly medical characters, especially if it goes to Brook-street or to Grosvenor-street. I believe Fagge was capable of any kind of excellence, and he might have been tempted out of true medical greatness into grandeur. His greatness as a physician became evident to observers of character very soon after his brilliant student career had placed him on the staff of Guy's Hospital; he did not merely constellate already known facts, but he found new facts. Former volumes of Guy's reports contain ample and most valuable proof of Fagge's greatness as a physician. His genius of eyesight, or power of observation if you will, was sustained by immense memory, and brought into action by vivid and constant suggestiveness of intelligence. I watched Fagge closely, and knew him to be one of the most dynamic minds of the age; certainly, second to none in our profession. Let me instance one fact in his career, not because it is the most brilliant, but because it will serve best to show those points of his character which I am endeavouring to draw attention to.

In Guy's Hospital Reports for the year 1868 appeared Fagge's papers "On Certain Rare Cutaneous Affections" and "On Keloid, Scleriasis, Morphœa, and some Allied Affections." It was at once recognised that these papers were the work of no mere bookworm. True, the literary knowledge of the subject would, indeed, do the highest credit to one whose reputation was to rest on his large reading; but the paper on keloid showed that Fagge meant more than reading. Dr. Addison had, many years before, recorded some cases of keloid, and models of these cases were in the museum. The course and consequences of keloid were, however, unknown. Fagge had seen cases of this disease, and amongst them one which had been in the clinical ward eight months before his paper was written. Whilst writing his paper he visited this patient at her home, and observed that the disease was ameliorated. Hereupon, it struck Fagge that the disease might be transitory, notwithstanding its tumour-like or scar-like appearance. And to learn whether this was really so he at once proceeded to search for Addison's patients of years before, tracing them to their homes, so that, aided by the wax models, which enabled him to know their condition in Addison's time, he discovered and proved that keloid is a temporary disease, and that the affected skin, with all its unpromising appearance, is capable of recovery. When I say that he made a journey into Hampshire in order to see one of these ancient cases of Addison, it will be plain that no common obstacles were likely to prevent Fagge from advancing medical knowledge. The general effect of his work on this branch was to bring together vague and scattered groups of rare skin diseases, and to show their relations to each other, and to arrive at certain conclusions from quite sound facts cleverly lit upon and laboriously followed out; so that Fagge's conclusions may be enlarged or modified by future facts; but the cases he watched to their completion will ever remain types of sound and careful observation, real additions to our knowledge. Let anyone read the papers I am speaking of, and he cannot fail to admire their earnestness and richness in new matter, their sterling honesty and conscientious accuracy, and most unwearying pursuit of all those possibilities for further advancing the question which can be arrived at by faithful discussion of the subject; and every reader of Fagge's papers must indeed be struck, not only with his patient truthfulness as an original scientific observer, but with his literary honesty. Fagge never, in the ardour of any inquiry or in the heat of any phase of competition, forgot to listen to the conscience of an honest man and a gentleman. He was the very genius of candour and truthfulness, of truest modesty. You may read all his papers, and never once will you come across any exaggeration such as worse than falsifies half the medical work that sees the light in our press. He gave to every predecessor in the field all credit that was due. Indeed, his always generous desire to do justice often induced him to credit those he cited for a completeness of idea which in truth belonged properly to himself; so that, in the place of Harvey, I think Fagge would have credited to Cæsalpinus the whole circulation of the blood, and so have saved the labours of those who now seek to acquire for their Italian fellow-countryman a credit that does not properly belong to him.

Fagge had a great memory and great power of application and magnificent honesty, and so there was in him much that goes to make the great, if not the grand, physician; and although there was perhaps something lacking in him which you are accustomed to see in grand physicians, until you are disposed to think it to be of the very essence of medical greatness, yet, in truth, he was not only a great but a successful physician. Steadily he made his way amongst all possible competitors for true greatness, and it was already well known to his contemporaries whose reputation amongst them all would best stand the test of time. His splendid gifts made trickery unnecessary as a means of high ambition. He was such a man as vindicates the truth to nature of that unsparingly severe story known as the parable of the talents. Those less highly endowed have so much excuse for envy, that they might well think it better for their happiness to hide away their poor little natural gifts. But although we are taught that such is the usual and first temptation of very small talents, so that no usury is got from them, it is not meant that this is always the case. In some rarer instances we see the clever possessor of one talent manage to make up with borrowed capital, and so get a surprising percentage on his little talent, enabling him to appear quite rich, with all the fussiness and want of modesty that mark the *parvenu* of science; till high interest proves false security, and the little man's real capital some day disappears, and what he had is swallowed up in what he only seemed to have, and he becomes a mere phantom and a show before his fellows.

I cannot pass on without remarking upon that very curious tendency of "self" to identify itself with its acquired possessions, whether these are stores of learning or such more obviously external property as the clothes from one's tailor. It is so very curious to see how a child prides itself on its new scraps of information, identifying itself with the acquisition just as it also prides itself on its nice new frock,

Digitized by Google

and conceives itself with information, frock and all included. And so grown children identify themselves with all they have picked up in the way of knowledge just as they do with the clothes they are wearing. And how complete is this latter identification you may best imagine when after death their ghosts appear generally in these clothes. Mr. S—— recently saw the ghost of a soldier in full uniform; also, a clerk in the Bank of England saw his brother's ghost in dress clothes—truly most curious parts of a spiritual individuality; but really, when one comes to think, they are not more really foreign to the individual himself than most of the remarks which mediums can get from departed spirits, which are always very secondhand remarks, and, indeed, merely what was put into the defunct by the communications of his fellows. In fact, I do not quite know what constitutes a pure individuality such as might appear to the spiritual eye as a true self. How little of what we call ourselves is truly alive; what proves immortal will be rather what moves than what composes angelic features. But when the uniform and dress clothes and scraps of information are stripped away, it is very difficult to form a conception of what will be left. I expect not much will be left of people who have no character. But Fagge was a man of character, and his life conveys a distinct and instructive idea. His gifts were no mere traps to catch fortune. He had little of the art of taking credit for lucky strokes which make you seem, even to yourself, to know more than you really do. He had vast natural abilities, and could afford to wait and to go steadily and easily. Indeed, if there was anything lacking in his career, it was that he perhaps worked with so natural an ease that he did not put himself out to be showy enough. I am thinking of what happened one day when I was trying to buy a horse at Seymour's Repository, at the fashionable part of the West-end. The proprietor was recommending me a handsome creature with beauty and power and pace, and all that I could see desirable in a horse at only 100 guineas. When acutely observing my disappointment at the low price, he said: "Only wants a little of what we call action, sir, and he will fetch 500." This for a moment set me reflecting how much a little of what a West-end judge would call action might do for many physicians gifted with form and power and pace; and I seemed for a moment to see with the mind's eye what in the West-end we call or might call "action" in grand physicians. If Mr. Francis Galton's machinery for making compound pathological photographs could have been applied to my mind's eye, I believe it might at that moment have recorded a valuable image of "action." It is meanness to smile at it. The smile is utterly unworthy. One really ought to carry a stock of spare reverence for use as supplement on occasions when one ought to feel reverence, but cannot quite rise to the required level; for so much, after all, in very truth, depends on how we act towards each other. This interaction constitutes the inter-reality which is the reality of social life, and in a sense we are to each other no more than the impressions we make upon each other. So, at least, you might be weak enough to think if there was in the world no earnestness like the earnestness that made Fagge a great, as distinguished from a grand, physician. He was, before all things, earnest in his work. It is earnestness that makes greatness. I don't quite know what makes grandeur; it is too subtle for my coarse analysis. But without earnestness there is no true greatness. In vain you try to lead a party with quips and sneers. The vulgarest Brummagem earnestness will push you aside. Earnestness taketh by force in the very kingdom of Heaven; and Fagge was before all things an intensely earnest man; and the earnest attaches to the real and moves the real, and whatever Fagge brought forward had a solid reality, which made it useful matter for all concerned. Few medical writers of his age are more frequently quoted, either in his own country or throughout Europe and America. Whoever had Dr. Fagge's facts to support him was sure at least of that part of his ground. His papers on "Intestinal Obstruction," on "Diseases of the Liver and Peritoneum," on "Croup and Diphtheria," and on "Diseases of the Heart" [illegible] be instanced as examples to show the scale on which he [illegible] other facts as raw material from which either he [illegible] following him might reach new and sound [illegible] Fagge's earnestness as a physician made [illegible] original in therapeutics. He was too much [illegible] healing spirit to stand by and see his patients die in accordance with pathology. One of his papers in the reports will show his readiness to initiate bold measures on his own responsibility. In a paper on "Diabetic Coma" Dr. Fagge describes the relief that followed when he injected warm saline fluid into the veins of a person comatose with diabetes. The patient returned to consciousness, and remained sensible until it was judged right to give him some codeia, when he again became insensible and could not be aroused. Dr. Fagge was not hesitative or feeble in therapeutics. But I believe I do his memory no wrong in saying that he never exhibited any enthusiasm for the elaborately theoretical treatment of outlying and superficial symptoms. He did not belong to those who weave interminable accounts of tiresome doubtful details upon the effects of drugs that might possibly be of some good in chorea, if only the remedies for chorea happened to be the same as the remedies for wriggling, which, in the meantime, we know they are not. But Fagge tried honestly his best to relieve his patients with effectual remedies. He was not by any means the man to treat clinical medicine in a spirit of scientific despair, as is the manner of some who teach it so that meaner minds will obtain the despair without the science. He was always ready in the invention of new measures of treatment. Those who write originally on therapeutics may be divided into: (1) Those who love relieving the sick; (2) those who are set upon the laws of action of the drug; and (3) those who wish to push some new remedy for the sake of a name. Of course, all these motives may be blended together in various proportions, but it is generally pretty evident which of them constitutes the true actuating power. Fagge, in his therapeutical teaching, like a true physician, was always plainly actuated by the first and purest of these motives. I will not speak in disrespect of the second kind of motive. Dr. Fagge did good work in this direction. The paper which he, with Dr. Stevenson, wrote on the action of digitaline[2] was no mean contribution to the then existing knowledge of a most important subject. No doubt it is necessary that the doctor should have a clear conception of the range and measure of power belonging to each of the drugs he uses, just as he should have a clear conception of the extent and character of the diseased changes which he means his remedy to reach and combat. And one must not think slightingly of any sound work done seriously and earnestly to measure the size and form of a remedy any more than we think slightingly of pathological work done to estimate the depth and characters of particular diseases. There is something absurd, but for its obvious danger, in throwing drugs of imperfectly known power after diseases whose nature is as little recognisable. Mr. Mill smiled at another philosopher for describing digging as the insertion of the idea of a spade into the idea of the ground. But in much of our treatment do doubt the idea of the remedy is inserted into the idea of the disease when nothing really exists corresponding to the ideas with which we suppose ourselves to be acting. Of course I here speak of treatment as distinguished from cure in the line of distinction so well drawn by that able physician, the late Dr. Peter Latham. When we have a known cure for a known disease we use the cure whenever we meet the disease, and there are no ideas worth speaking of in the whole matter. But when there is no known cure for a disease, we have to form an idea of the disease, and meet it with the idea of a remedy. And although this proceeding is not, as a rule, very satisfactory, yet we have no right to think trivially of a branch of inquiry which tries to give us more definite ideas of the powers of our remedies. Dr. Fagge's work on Digitalis was a good example of the best sort of this kind of work. He was young when he carried it out, and this branch of activity was not followed up by him. The distinction which Dr. Latham drew between cure and treatment is in a half-conscious way recognised by the public. When you can cure the patient he approves of you, and says you know his complaint. When you know no cure for him, but proceed to treat him, he is apt to call that being experimented upon, and to put on an air of doubt and resentment. The public watch jealously all experimental treatment. The justification of it is a matter of conscience, and the public is always ready to impose its conscience on private individuals. Yet the physician is expected to heal. His place at the point of contact between nature and human nature is a delicate and difficult one; and compelled as he is to study nature for the corporeal good of humanity, he must not too sorely try its spiritual side—that spiritual side of humanity which we always hope may prevail as the most

[2] Proceedings of the Royal Society.

Digitized by Google

truly human element in our compound nature. Instinctively mankind feels at one with all living things. The love which the world has for science is cold compared with the love with which humanity loves nature—the visible, audible, sensible world; the world of taste and touch which we call nature. It is a beautiful name; it was invented long ago in some golden age; nature, the growing, in such contrast with fabric of all kinds; the sensuous presence of this world in which we live, and out of which we die; the consciousness of which constitutes life to each of us; nature, which we try to analyse in science and to imitate in art, but which ever escapes our analysis and distances all imitation. The clever chemist will take a natural object, say a feather, to find out what it *is*, and he will burn it under certain conditions and collect the results, and measure and weigh, and end by getting the feather into things he supposes he knows better, which he calls carbon, oxygen, nitrogen, and hydrogen. The very special feather has reached its place in his very general generalities; but of the nature of the feather whereby it had its shape for the eye and its resistance to the touch, and its resiliency and all else that makes up feather-nature, if you ask the chemist for this he will bluntly accuse you of metaphysics, which in five-sense science is a heresy. The clever artist, on his part, will paint with lilac paint to represent the distant hills, and will grow so sure that his lilac paint is like the distant hills that he will almost think the distant hills are like his lilac paint; until he never again will see the distant hills as they are, but only as he paints them. Nature, who yields so little to analysis and is so far above imitation, is one with us all in this life of ours, and waits always at our senses full of instruction, which is not mere science, and of beauty which defies all art. And the mode in which we are influenced by sensuous nature constitutes in each of us his character. Your character is what you are and feel amongst the things of the world and amongst men as things. True, a generation is rising in Board Schools in great cities, which in place of natural character will have what? Well, what? I don't know. Nature seems likely to be hidden under brickfields and dustheaps, and character to be lost in science limited by art—in secondhand science limited by secondhand art. What will the future of it all be? Mr. Matthew Arnold, his lips touched from Isaiah as Isaiah's lips were touched from the altar, gives a prophecy, a secondhand prophecy, and says: "There will be a remnant." Well, if so, the remnant will be those who, like Fagge, have character which makes them work real work amongst the realities of their actual calling; those who live as real natural live human beings, and not mere phantoms of science and art. For what is this life of ours out of which Fagge is gone? And what this individuality which places us in it, if not some sort of shadow cast in some sort of light; the cause of which shadow being removed, we shall all be one in the light?

"Bradshawe" Lecture

ON THE

PATHOLOGICAL RELATIONS OF THE ABSORBENT SYSTEM.

Delivered before the Royal College of Physicians of London, August 13th, 1884,

BY G. HARE PHILIPSON, M.A., M.D., D.C.L.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS,
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF DURHAM, SENIOR PHYSICIAN TO THE NEWCASTLE-UPON-TYNE INFIRMARY, ETC.

(*Concluded from p. 311.*)

THE lymphatic vessels are subject to two principal classes of tubal changes—namely, dilatation and hypertrophy, and obstruction. Dilatation may affect the capillary network of the lymphatics; more commonly the larger trunks; or occasionally the thoracic duct or the receptaculum chyli. It presents various degrees and assumes different forms. Thus there may be merely a localised reticular dilatation of the lymphatic capillaries; or more frequently varicose, saccular, tubular, fusiform, or cirsoid dilatation of the trunks; or the enlarged vessels may form a distinct growth, named lymphangioma or lymphangiectodes, which has been divided by Wagner into the three varieties, simple, cavernous, and cystoid, in which cysts are developed. Moreover, enlarged lymphatics constitute an important element in the structure of elephantiasis and other growths, especially elephantiasis lymphangiectodes. The thoracic duct and receptaculum chyli may be enormously dilated, the former in extreme cases reaching the size of the little finger, or even attaining larger dimensions than this. The deep lymphatics and the lacteals are liable to dilatation, as well as those on the surface. Lymphangiectasis is in many cases congenital, and it has been supposed that this may be due to the want of specialisation in the lymphatic system of certain parts. The condition is attributed to different causes. Thus it may follow lymphangitis, in consequence of which the larger tubes are blocked, and the afferent vessels therefore become dilated. In other cases it is not preceded by marked inflammation of the lymphatics, but there is considerable hypertrophy of the cellular tissue, and the vessels enlarge, forming a very free anastomosing network. Again, it is supposed that dilatation may arise from nerve hypertrophy of the lymphatic plexuses, or from paralysis of the coats of the vessels. Any obstruction from internal plugging or external pressure may lead to enlargement of the vessels, the circulation through which is thus impeded; and probably the obstruction may be occasionally seated in the glands. Lymphatic dilatation is most frequently met with in warm and moist climates. When lymphangiectasis occurs on the surface of the body, it can be recognised by objective examination. Dilatation of the superficial lymphatics is generally observed on the inner side of the thigh, the sides of the abdomen, the scrotum, and the penis. It is characterised by vesicles like grains of sago, grouped irregularly (Curnow). Sometimes only ampullæ are formed, which are generally soft and painless. The vessels may rupture subcutaneously, forming vesicles containing a clear or milky fluid. They are also liable to rupture externally, or into various internal parts when situated internally, and it is only thus that the latter can be at all recognised clinically, the escaped chyle or lymph appearing in the fæces or urine. Even superficial dilatation of the lymphatics has been not uncommonly mistaken for other conditions, such as herniæ, abscesses, and strumous enlargement. The discharge of lymph confirms the diagnosis. If inflammation attacks dilated lymphatics, it tends to spread rapidly, and may prove fatal.

Multiple lymphatic nævi of the skin, a newly observed disease of the lymphatics, has been recently described by Hoggan. The condition is believed to be not uncommon, quite as frequent perhaps as venous nævi, which it often accompanies and complicates. It also forms the initial stage or predisposing pathological condition of other diseases, such as lymphatic varix of the larger vessels, and also of elephantiasis, in the production of which it may often be the most important factor. That this has not been observed before is probably due to the fact that no proper histological examination, as apart from microscopical, has been made of the tissues in the initial stages of the diseases. That the condition has not been recognised clinically is probably due to the want of colour in such nævi, as compared with venous nævi. But there can be little doubt, from the frequency with which venous nævi have been observed in elephantiasis, that the two conditions of venous and lymphatic nævi are generally coexistent, and that conditions of hypertrophy, due really to the latter form, have, through being unrecognised, been erroneously ascribed to the former. On the other hand, when the lymphatic nævi were small, and placed so superficially in the skin that distension by lymph, produced at will, made them appear above the general surface, like vesicular papules, such a condition would almost certainly have been described as "varicose lymphatics."[1]

The absorbent vessels may become obstructed. This condition may involve the lymphatic capillaries, their main trunks, or the thoracic duct itself. It may result from the blocking up of their channels by coagulated lymph, from inflammation of the walls of the vessels, or from external pressure. Thus the thoracic duct may be more or less obstructed, or even completely obliterated, by the pressure of enlarged glands in the thorax, or of an aneurysm. The lymphatic trunks in the limbs may also be compressed by glands, aneurysms, and other morbid conditions; and also the capillaries are subject to pressure in consequence of inflammation of the surrounding cellular tissue. Obstruc-

Digitized by Google

tion of the thoracic duct is said to arise from disease of its valves. It may be remarked, further, that a certain degree of obstruction to the flow of the lymph and chyle may arise from marked interference with the venous circulation, as the result of cardiac disease or direct obstruction of the principal veins. If the thoracic duct be obstructed, and if the chyle cannot reach the venous system by the establishment of a collateral circulation, grave general symptoms arise—namely, marked wasting and anæmia, tending towards a fatal issue. Various degrees of obstruction of this channel have, however, been found in several cases at post-mortem examinations, in which no symptoms had been observed during life. The most obvious direct effects of obstruction in the absorbents are dilatation of the vessels behind the impediment, in the course of the circulation, and the development of lymphatic œdema. These conditions necessarily vary much in their extent and degree, according to the situation and character of the obstruction. The dilatation may ultimately lead to rupture of the vessels.

When lymph or chyle is discharged from the vessels or glands, either on the surface of the body or into some internal part, the amount varying much in different cases, the term lymphorrhagia or lymphorrhœa is applied in signification of the condition. Lymphorrhagia has been observed as a consequence of a wound, but more commonly of engorgement from closure of the lumen of the duct by inflammation or a tumour. In rare cases it may occur from slight wounds, especially in the neighbourhood of joints, which is probably due to a constitutional defect, a lymphorrhagic diathesis corresponding to the hæmorrhagic diathesis (Bradley). Usually traumatic lymphorrhagia results from wounds of the thoracic duct, of the larger lymphatic trunks, or of the glands. Idiopathic lymphorrhagia is generally due to previous dilatation of the vessels, which ultimately give way. A most interesting case has been reported by Cayley, in which the receptaculum chyli gave way spontaneously as the result of previous extreme dilatation, and fatal peritonitis ensued.[2] Lymphorrhagia may be associated with chyluria, and is then believed to be due to the filaria sanguinis hominis. When lymphorrhagia occurs on the surface of the body, the discharge of the lymph is the clinical sign of the condition. The amount of fluid which escapes varies considerably, ranging from one ounce to five or even ten pounds during the twenty-four hours. It also differs at different times, and the flow has been known to assume a periodic character, increasing during digestion. The fluid which escapes after injury may be clear and limpid lymph, or mixed with inflammatory products or blood. That which comes away in cases of rupture from dilatation of the vessels is more or less white and milky, like chyle, and it contains a variable quantity of fat. The quantity of fibrin present varies much, and therefore the power of spontaneous coagulation of the fluid. When lymphorrhagia takes place internally, it can only be recognised by the presence of the fluid in the urine or fæces respectively—in the former case giving rise to chyluria, and in the latter to fatty stools. Bradley directed attention to the probable origin of certain cases of hydrocele, hydrocephalus, pleuritic effusion, and ascites from a lymphorrhagia into the respective serous cavities. As proved by Cayley's case, the escape of chyle into the peritoneum may set up fatal inflammation. The general condition is more or less affected in cases of lymphorrhagia in proportion to the amount of fluid lost.[3]

The consideration of inflammation of the lymphatic system would now appear to be appropriate. Acute inflammation presents three varieties—namely, where the vessels are alone affected, lymphangitis or angeioleucitis; where the condition is limited to the glands, adenitis; or where both vessels and glands are involved. It will be convenient to consider these varieties together. As a rule the disease is localised, but under certain circumstances the absorbent system is more or less widely implicated, especially if the inflammation be of a septic character. It may be set up and extend with great rapidity.

This class of affections may be of traumatic origin, being due to various forms of injury, such as a wound, contusion, or strain; or they result from various kinds of irritation, such as that produced by neighbouring inflammation, suppuration, ulceration, or diseases of joints or bones. The implication of the glands under the jaw, in cases of diphtheria and scarlatina, is a familiar illustration of irritation from within. External irritation, as, for instance, the strong heat of the sun, may induce superficial lymphangitis. Special forms of inflammation of the absorbent system are set up by specific kinds of irritation, such as that of the syphilitic virus, and septic forms of the disease are induced by various septic poisons. The lymphatics connected with the internal organs are often inflamed when these are the seat of any irritation. Pus has been found in the neighbouring lymphatics in cases of purulent pleurisy. Some forms of pelvic cellulitis have also been regarded as being due to lymphangitis. Inflammation may be immediately excited in the vessels and then travel along to the glands; or the irritation may be conveyed by the current of lymph to a more or less distant part, the intervening portion being unaffected, or the glands may be implicated by extension from the surrounding tissue. When a gland is involved while the vessels between it and the source of the irritation are unaffected, the inflammation is said to be sympathetic. Inflammation is much more readily excited in the lymphatic structures in some persons than in others, and especially in those who are of a strumous habit. The glands are more liable to be affected in the early periods of life. A low state of health may predispose to inflammation of these structures from slight causes.

Lymphangitis is distinguished as reticular or tubular, according as the fine capillary network or the trunks of the vessels are involved. In the former case the skin and its capillaries are usually implicated. In the latter variety the vessels become dilated and their walls are thickened, the endothelium often disappears, and the internal coat becomes opaque and uneven. The lymph coagulates in their interior, blocking up their channels, and the clot may become organised, obliterating the vessels permanently, or occasionally it softens and suppurates in the centre, and the pus may find its way into the circulation, leading to septicæmia or pyæmia. Exudation also takes place, while the surrounding cellular tissue undergoes hyperplasia and becomes thickened. Lymphangitis may lead to inflammation in joints, which may be of a purulent character. In adenitis the affected glands become congested and swollen, as well as the seat of exudation, while the passage of the lymph through them is impeded. Resolution may take place after a time, but not uncommonly the inflammation terminates in suppuration, this beginning in the centre, the cavities of the glands becoming filled with pus, and the surrounding cellular tissue being also involved. In other cases the glands remain more or less indurated, and they may form adhesions to the surrounding structures, especially if the irritation is repeated several times. Glands which are chronically enlarged, as the result of inflammation, are very liable to become the seat of acute inflammation from slight causes. They may subsequently suppurate or undergo a caseous degenerative change, but often remain unaltered for a considerable time. This condition of the glands interferes with the passage of the lymph through them.

When the superficial lymphatic vessels or glands are inflamed, this condition is evidenced by objective signs. Lymphangitis is indicated by wavy or straight lines, running towards the glands, or sometimes there are isolated red patches, the skin and its capillaries being involved along with the lymphatics. The large vessels may be felt as firm and knotted cords. If the glands are affected, these can be felt, and are seen to be more or less enlarged and swollen, at first feeling firm. At the same time pain is experienced, often very acute, with sensations of heat, stiffness, and tenderness. When the affected structures are deeply situated there are no red lines, and redness is not always present. There is induration of the part, more like that of œdema than inflammation. The inflammation may, however, pass through the intervening tissues from the deep to the superficial lymphatics, and *vice versâ*. Owing to the interference with the passage of the lymph more or less swelling from lymphatic œdema is often present, of a firm character, and a limb may be much enlarged from this cause. If suppuration should take place in the glands, this will be evidenced by the ordinary signs characteristic of an abscess. There is more or less pyrexia, in proportion to the extent and intensity of the inflammation. In septic forms of lymphangitis signs of general septicæmia are likely to arise.[4]

In reference to the morbid conditions of the lymphatic glands, manifested by enlargement, if we have regard to the anatomical characters, there are at least three which it is

extremely difficult, and often impossible, to distinguish from one another. These are simple inflammatory hyperplasia (lymphoma), the so-called scrofulous form of enlargement, and that morbid condition now generally known as lymphadenoma.

Lymphoma is a comprehensive term, and includes formations which are not strictly tumours, but rather hyperplasias of the tissue proper to lymphatic glands, lymphadenoid, or, briefly, adenoid tissue, as it is called. Lymphoma as a neoplasm would imply the development and deposit of new adenoid tissue in the form of a tumour within a lymphatic gland or follicle, or some other structure of the connective tissue group. In what is usually called lymphoma this does not happen. What does happen is that the tissue of the lymphatic gland or follicle increases in size because the lymphoid cells it contains are multiplied, while the reticular tissue undergoes hyperplasia. The process is often inflammatory in character; in other cases the lymphoid hyperplasia seems to begin idiopathically—that is, without any cause hitherto discovered. It may often be doubtful whether the increased growth of a lymphatic gland should be regarded as neoplastic or as hyperplastic. Many cases of lymphoma, especially the leukæmic kinds, seem referable to hyperplasia. The lymphatic glands, adenoid structures of the intestine, and lymphoid follicles of the spleen, all maintain their structure as they grow in size, or alter but slightly. Moreover, the functions of the glands seem to be more actively performed. This does not seem to indicate that they are invaded by anything of the nature of a neoplasm.

In addition to the hyperplastic lymphomata, there is a true or heteroplastic tumour, whose structure agrees with that of lymphadenoid tissue. As the term lymphoma has been perverted to describe the hyperplastic formations, we may do well to distinguish the genuine tumour as lymphadenoma or lympho-sarcoma. It is a sarcoma whose structure somewhat resembles that a of a lymphatic gland. It most commonly originates in lymphatic glands, and in the adenoid tissues of the mucous membranes; it may, however, arise elsewhere. When it attacks a lymphatic gland it may be distinguished from mere hyperplastic lymphoma by its rapid growth, and by its tendency to overpass the limits of the gland and to form metastases.[5]

The term scrofulous is commonly applied to the slow and painless enlargement of groups of lymphatic glands, which occur for the most part in children, and almost invariably ends in the destruction of the glands by an imperfect kind of suppuration. Scrofulous glands are generally met with in either the neck, thorax, or abdomen, and are commonly limited to one of these regions. Indeed, in the neck, where their progress can best be followed, we often see that the enlargement commences in one gland only; that the glands in the vicinity are successively affected, and often at long intervals; and that after a while the morbid process ceases with the destruction of all the implicated glands, those on the opposite side of the neck possibly remaining all the time perfectly healthy. In the earlier stages of the affection the glands differ little, either to the naked eye or under the microscope, from such as are simply hyperplastic from inflammation, but they tend soon to become opaque, yellow, and friable, and to undergo caseous degeneration. This change commences in the central parts, and gradually involves the whole mass, which presently breaks down into a semi-fluid detritus. Occasionally the caseous swelling dries up, earthy salts are deposited in it, and it becomes an inert earthy concretion. There is a good deal of vagueness in the sense in which the term "scrofulous" is generally employed. It is taken for the most part to imply that the morbid process to which we attach it is dependent upon some peculiar condition of the constitution, and, further, that there is some close affinity, if not actual identity, between it and tubercle. But the so-called scrofulous glands are certainly not tubercular, and although their appearance is sometimes followed by that of tubercle, in a very large number of cases no such sequence is observed. As regards cachexia, it is certain that scrofulous glands often develop in persons who appear in all other respects in the best of health; and, furthur, if we may judge of the limitation of the morbid process, that if we admit their dependence on a pre-existing state of cachexia, that cachexia must in many cases be limited to a definite part or district of the organism. It is well known, moreover, that when a single gland has undergone scrofulous proliferation there is a remarkable tendency for the morbid process to spread thence to other glands in its immediate neighbourhood, and thence again to others; it seems in fact to spread from gland to gland, through the agency of some infective material, which the diseased organs evolve. It is well known, also, that scrofulous enlargement of the glands of the neck not unfrequently follows upon certain diseases affecting the throat—such as parotitis, diphtheria, and scarlatina. Now, basing his arguments upon such facts as these, Virchow maintains, and I think with reason, that scrofulous proliferation of the lymphatic glands, like ordinary inflammatory hyperplasia of the same organs, is always secondary to some peculiar process going on at the mucous surface or other part which is in direct relation with them by means of the lymphatic vessels; that scrofulous disease of the glands of the neck is traceable to some inflammatory condition of the throat, fauces, or contiguous parts—of the bronchial and mediastinal glands, to pulmonary or bronchial inflammations, and of the mesenteric and retroperitoneal glands, to similar conditions of the alimentary canal. He considers that there may be some specific quality or element in the primary inflammation, and a tendency in its products to undergo rapid decay similar to that which characterises the morbid products of the diseased lymphatic glands, but that generally they are not recognisable, from the fact that in this case the cells are mostly developed at a free mucous surface, and are speedily shed from it. But he considers, further, that there may be some special aptitude or weakness, congenital or acquired, in the lymphatic glands of certain persons, or of certain parts of them, which makes their inflammations, induced by indifferent causes, assume the scrofulous character.[6]

In contradistinction to the scrofulous enlargement, tuberculous lymphadenitis may be mentioned. It attacks certain parts of the lymphatic system rather than others, especially those through which the lymph is as it were filtered—namely, the lymphatic glands. It is in the glands that the tuberculous eruption is most intense. Generally the process makes a kind of halt at these gland stations, but it sooner or later finds opportunity to spread onwards, and at length reaches the main trunks and the thoracic duct itself. Wherever the tuberculous process has become established, it is distinguished by the development of tubercles, and this in the lymphatic vessels as well as the glands. A more or less intense inflammation of the surrounding tissue is always associated with the tubercular eruption; it is manifested by hyperæmia with infiltration and swelling. If the process lasts for a certain time, it not unfrequently happens that young connective tissue is developed at the seat of eruption. The usual fate of the tuberculous growth is caseous necrosis, and disintegration. It rarely issues in the formation of fibrous tissue, and still more rarely in complete resorption of the tubercle. The virus which engenders tubercle may be carried out of the lymphatic system into the blood, either from a tuberculous focus in a gland or a tuberculous ulcer in the thoracic duct. It may thus be conveyed to distant organs.

In the morbid condition known as lymphadenoma the enlargement of the lymphatic glands consists at first of mere hyperplasia, and subsequently of fibroid induration. It varies much in its extent. A few glands only may suffer, or every gland in the body may be enlarged. The former cases have the character of a local growth, the latter is distinctly a general disease, for which the term "lymphadenosis" seems the most exact. The glands vary in consistence; when soft, there may be a considerable excess of leucocytes in the blood; when hard, there may be simple anæmia. Microscopic examination reveals that the enlargement is due to hypertrophy of the glandular tissue, the whole structure being converted gradually into lymph cells, with a fine network of cellular tissue. In addition to the hypertrophy of the glands, other organs in course of time present growths of a similar nature, especially the spleen, and less commonly the liver, lungs, kidneys, and alimentary canal. Even the canals of the bones may be filled with lymphoid cells. Very little is positively known as to the etiology and pathology of the condition; but it is assumed that it is a primary affection of the lymphatic system, depending upon some special constitutional condition or diathesis, named lymphadenosis. By some pathologists it is regarded as malignant, and is placed by Wilks between cancer and tubercle. In many cases the disease seems to begin without any obvious cause, but in

others it evidently starts from some local irritation, and such irritation has probably been present in other instances where it has been too slight to attract attention. As regards predisposing causes, the disease is most common in early and late adult life, in males, and amongst the poor, its development being aided by bad food, insufficient clothing, cold, and damp, and unfavourable hygienic conditions. When the affected glands are superficial, their enlargement is evident on objective examination, and their extension and growth can be observed. In the large majority of cases there is neither pain nor tenderness, but if the enlargement is very acute and rapid, sharp shooting pains may be complained of. When situated in internal cavities, the existence of lymphadenomatous growths can generally be made out by physical examination. Some of the most important symptoms result from pressure and irritation by the enlarged glands, these necessarily varying according to their position and their relation to adjoining structures. Obstructive dyspnœa is often a marked symptom when the growth is situated within the chest. Along with the local signs of the disease, the constitution is obviously affected as a rule. This may occur before any local symptoms appear, but usually the general symptoms are gradually developed as the glands progressively enlarge, including emaciation, anæmia, and its attendant phenomena, often combined with an appearance of serious illness, marked muscular weakness, the patient often tottering and trembling, and feeble circulation. More or less pyrexia is present in most cases, especially in young patients. Free perspirations are common, and the skin is pale and usually moist. Œdema of the legs is a frequent symptom. The blood does not present any excess of white corpuscles, but is often very watery and wanting in its normal colour, the red corpuscles being markedly deficient. The patient is much depressed and low spirited, and attacks of syncope are not uncommon. Bronzing of the skin arises from enlarged retro-peritoneal glands surrounding and compressing the solar plexus. Unless death should occur from the local effects of the enlarged glands, the course of the disease is generally chronic and progressive. In most cases death occurs within two years, either from gradual asthenia and exhaustion, from the effects of pressure, rarely from hæmorrhage, owing to perforation of a bloodvessel, or from some intercurrent complication, such as pneumonia, pleurisy, erysipelas, or kidney degeneration.

Hard lymphadenoma or lympho-sarcoma occurs as a primary growth most frequently in the superficial lymphatic glands. Other groups may be attacked in the further course of the affection. For example, if the affection start in some of the cervical glands, the rest of the cervical glands and the thoracic and abdominal glands lying near the large vessels are attacked in succession. The glands are transformed into firm, tough, elastic, or hardened knots, forming dense clusters in combination. Single glands may reach the size of a walnut. On microscopic examination the lymphadenoid structure is seen to be preserved, while the cells are increased in number and the reticulum is thickened. Fatty degeneration, calcification, or softening rarely supervenes. In later stages the follicles of the spleen may be affected, and be changed, like the glands, into hard nodules. The spleen is never primarily affected in this form of lymphadenoma.

Sarcoma of the lymphatic glands is a somewhat uncommon affection. It occurs in single glands, or several of the same group are simultaneously affected and cohere into a nodular tumour. It often overpasses the limits of the gland and invades the adjoining tissues. Secondary growths are usually developed; small round-celled sarcoma, spindle-celled sarcoma, fibro-sarcoma, and alveolar sarcoma, or alveolar baglo-sarcoma are all forms which occur. All the forms of tumour which give rise to metastases may affect the lymphatic glands. Cancers especially are apt to do so, and the glands become enlarged and altered as the disease advances. Sarcomatous metastases, like the carcinomatous, may originate in sarcoma cells which have entered the gland through the lymphatic vessels.

THE following lecture demonstrations will be given in the Hygienic Laboratory of the International Health Exhibition during the forthcoming week, by Mr C. Cassal, F.I.C., F.C.S., Sept. 2nd, Arsenic in Wall Papers and articles of Clothing; Sept. 3rd, Drinking Water; Sept. 5th, Common Food Adulterations. The lectures will commence at 4 P.M.

ON A CASE OF PISTOL-SHOT WOUND OF THE CEREBELLUM.[1]

By WILLIAM THOMSON, M.A., F.R.C.S.,
SURGEON TO THE RICHMOND HOSPITAL, DUBLIN; GENERAL SECRETARY TO THE ACADEMY OF MEDICINE, IRELAND.

ON Nov. 26th, 1882, I was asked by the authorities to assist Dr. Egan in making a post-mortem examination on the body of a detective officer, who had been shot on the previous evening during an attempt by him and his comrades to arrest a number of suspected men. He was carried to a neighbouring hospital, and being then dead, the body was transferred to the morgue, where the autopsy was held on the 27th. On external examination a small round wound was found in the occipital region, about an inch to the right of, and an inch below, the occipital protuberance. There was no mark of powder on the scalp, or anything to indicate that the shot had been delivered at close quarters. On reflecting the scalp, and thus exposing the aperture in the bone, I found a piece of lead upon the right margin of this opening, and tolerably firmly fixed to the bone. For the time, this was left *in situ*. The calvaria was then removed. This was a very difficult operation, because the dura mater was closely adherent, and a great deal of laceration of this membrane was unavoidable. Between the dura mater and the right parietal bone was a considerable effusion of blood, showing some wound of a meningeal vessel. The brain was next removed and inspected. Corresponding to the wound in the occipital bone, the right lobe of the cerebellum was pulpy and disintegrated for a depth of half an inch. Some small fragments of bone and lead were found in the débris. The portion of lead referred to as attached to the occipital bone was examined, and was found to consist of the anterior half of a revolver bullet. The apex was directed towards the right and slightly upwards, the base was oblique and had evidently been thus cut and shaped by the edge of the bone. The bullet had apparently impinged upon the part at a very acute angle, had crushed in the bone, and in its onward course had met with the sharp margin of the hole so made and been divided upon the right edge where it was found. The remainder of the bullet was not found at this time. The cerebellum was carefully sliced, then the right hemisphere, but no trace of the missing portion could be found in either of these parts. The left hemisphere was then examined from above downwards, slices being made as before, and it was only on coming to the inferior part of the anterior lobe of the left hemisphere that the edge of the knife struck upon a piece of lead. This proved to be the remainder or basal portion of the bullet. It was embedded in the superficial part of the brain substance, to about its own depth, with the base directed inwards, and the cut surface, which corresponded to that already described in the other portion, directed outwards. The question arose how the fragment got there, having entered on the right side of the occipital bone, and a careful examination of the sections of brain was made, but no track of a passage through the substance of the organ could be found. A second wound was found on the left arm a little above and between the olecranon process and the internal condyle. This was traced upwards to the armpit, and a bullet was found lying behind the pectoralis major as it forms the anterior boundary of the axilla. A contusion on the left forearm was the only other mark of violence.

The point of surgical interest in this case, thus far, is as to the course of the basal fragment of the bullet found embedded in the brain. I have stated that there was no trace of a track through the organ by which the bullet could have passed; and we are therefore driven to the conclusion that the fragment moved round the inner surface of the vault of the skull, between the dura mater and the bone, until it was stopped where I found it. The adhesions of the dura mater rendered laceration unavoidable, and I was therefore unable to determine any openings made by the bullet in that membrane. But the effusion of blood under the right parietal bone showed that some rupturing force had been introduced there, and there was in addition a very distinct

Digitized by Google

lead patch, on the inner surface of the same bone, showing that lead had traversed that region. We are all aware of the fact that bullets are very easily deflected from their course, and that they especially adapt themselves to curved surfaces, if, with a certain velocity, there is present a sufficient restraining or directing material even so soft and pliable as muscle. Here the course of the bullet was from left to right, and the division of it took place when it struck upon the right margin of the bone wound. The anterior portion remained adherent there; the basal portion was deflected inwards, but continuing its course with diminished velocity dissected its way, so to speak, between the dura mater and the bone, to the position in which it was found. This is a very remarkable occurrence, and it is especially so when we remember that the sinuses which had to be crossed in the course escaped uninjured. That it is possible, however, is quite clear. Dr. Thomas Little has directed my attention to a case of a somewhat similar character, and as it is the only one that I have been able to find I may refer to it here. Baron Larrey reports that a soldier was struck in the middle of the forehead by a ball which penetrated the os frontis and then passed obliquely backwards between the skull and the dura mater, in the course of the longitudinal sinus, as far as the lambdoidal suture, where it stopped. Larrey traced the situation of the ball by the introduction of a gum elastic catheter into the opening; and measuring the distance between the fracture and the place where he felt the ball, he cut down upon that part of the skull beneath which he concluded that the ball was lodged. The bone was then perforated with a large trepan, a good deal of pus was discharged, the ball was extracted, and the patient recovered.[2] This bears out very strongly the view I have taken as to the course of the bullet in this case. It has been suggested that the bullet did traverse the brain substance and that the track had closed; but, as I have said, careful search was made for any trace of a passage through the organ, and none could be found. There would at all events have been some sign of contusion shown by small effusions from the torn vessels, but not even this was discoverable. The original course of the bullet was also undoubtedly from left to right and somewhat upwards, as was shown by passing a catheter into the wound before any incisions were made, and by the position of the anterior portion of the bullet when found. It is unnecessary to adopt such a theory as I have just referred to, when we have sufficient data to show that the course here described was not only possible, but that the facts before us prove the bullet to have taken the direction I have indicated.

But more important than the surgical are the medico-legal questions which arise in this case. In order to make these intelligible, I may shortly mention the circumstances under which the wound was inflicted. A number of detectives were anxious to follow a body of men whom they suspected. The officers were on the right hand footpath, the suspects on the left. They were both proceeding in the same direction. The detectives crossed the street obliquely towards the other men, and when the former were still in the carriage way, one of the persons followed turned round, stepped into the channel, and facing the first detective, but standing at the left side of the officer as he advanced, fired. At the moment that this took place it was sworn that the deceased, still moving onwards, had turned his head to the right in order to extract a revolver from his side-pocket, where it had been caught in his effort to draw it. But it was further sworn that after this first shot the deceased advanced upon his assailant, and fell upon him, both going to the ground. There was much firing then, and the prisoner was struck twice.

Now, the first difficulty in the case arose from the fact that the prisoner's revolver had only one discharged cartridge, while I found two bullets in the body. One therefore must have come from the police, or from one of the companions of the prisoner. It was stated that there was general firing on both sides, and therefore the second wound may have been inflicted by either party, but certainly not by the prisoner. A comparison of the bullets might determine this question, but unless we had all the revolvers fired against the police for comparison it would be impossible to say whence the second bullet came. We have, however, nothing to do with that matter here. I may only mention, in order to make the narrative complete, that the man was then arrested, and although committed for murder, was only tried on the minor charge of firing a loaded weapon at the officer, and was convicted. The authorities had, from a comparison of the bullets, satisfied themselves that the fatal shot was not fired by the prisoner. We will suppose, however, that in this case both the bullets were of the same size and marking. The question would then arise, Which wound was inflicted by the person charged, who only fired one shot? The discussion of this point may be taken under three heads: 1. Could a person in the position of the prisoner have inflicted the wound on the back of the head? 2. If the wound in the cerebellum had been first inflicted, could the person so injured have made any advance? 3. Is a wound of the cerebellum necessarily an immediately fatal injury?

1. The answer to the first question cannot of course be quite satisfactory. In a struggle like this men are naturally excited, and the relative positions of two persons, as told by others also engaged in the affray, has always to be accepted with some modification due to the circumstances. But there appears to me to be no doubt that a wound such as this could be inflicted by one person upon another advancing towards him in the positions which have been described. The assailant was to the left front of the detective, who, it was sworn, had to turn his head well round to his right, in order to see what impediment there was to the removal of his pistol from his side-pocket. If you place persons in similar positions you will see how much of the back of the head is exposed to the individual standing on the left front. In this case the wound passed from the left slightly upwards and to the right, making a very small angle with the surface at the point of impact—in fact, if the head had been thrown forward half an inch the deceased officer would have escaped, or at worst have received a scalp wound. At the same time, however, there are other sufficient explanations of this injury, one of which is that it might have been inflicted while the man lay on the ground, back up, and with his face in the struggle turned somewhat to the left. Here a bullet coming from a person firing at either detective or prisoner as they lay on the ground might have produced the same results, and shown the same course.

2. If the wound in the cerebellum had been first inflicted, could the person so injured have made any advance? This is a question of the greatest importance, because in this case it was proved that after the first shot was fired the deceased advanced upon his assailant and reached him. The prisoner only fired one shot, and therefore upon this would largely turn the decision whether he had really produced the fatal wound. Now, in viewing this branch of the subject we must carefully consider what are the functions of the cerebellum. We know that this question forms a very debatable one in physiology. There are, however, certain ascertained facts which will help us to a decision. There is no doubt that some lesions of the cerebellum are attended by loss of coördinate movement. Flourens says: "I removed the cerebellum of a pigeon in successive slices. During the removal of the first layers there appeared only a weakness and want of harmony in its movements. On removal of the middle layers the animal exhibited a general agitation, without true convulsions. It made brusque and irregular movements, and continued both to see and to hear. On removal of the last layers the animal entirely lost the power of standing, flying, leaping, or walking, which had been gradually affected by the preceding mutilation. Placed on its back it was unable to rise. Instead of remaining quiet and immovable, like pigeons deprived of their hemispheres, it was in a continual state of restlessness and agitation, but could never make any determinate movements. ..... Sensation, volition, and intelligence remained."[3] We know, on the other hand, that in some cases of diseases of the cerebellum the patient does not exhibit any marked want of power of coördination. Andral has noted ninety-three cases of disease of the cerebellum, and on analysis comes to the conclusion that only one of them quite supports Flourens' theory that the cerebellum is the organ of coördination of movements.[4] Combette[5] gives the particulars of the symptoms observed in a young girl in whom there was complete absence of the cerebellum. This patient could stand and walk up to a short period before her death, and the only characteristic symptom noted was that *se laissait souvent tomber*. Another case reported by Bouillaud, and referred to by Longet and Vulpian, is that of Guérin, whose cerebellum was found after death to be almost completely destroyed by disease. This patient still retained the

Digitized by Google

power of coördination of movements, and could walk, only he was observed to reel and totter when he walked. In reference to this case Vulpian remarks: "Here we have a case in which the cerebellum was destroyed, and yet the patient could walk, though in an unsteady manner. But if this (Flourens') hypothesis were well founded, he ought not to have been able to stand or walk a step, for the combination of muscular contractions necessary for locomotion or maintaining the erect attitude ought to have been altogether impossible."[6] Ferrier, while admitting that lesions of the cerebellum cause disturbances of stability and locomotion, believes that the evidence from all sources tends "to show that the cerebellum is not specially concerned in the coördination of locomotion—a function which we have seen reason to localise in the optic lobes." It is necessary, however, that we should observe a distinction between injuries suddenly inflicted and diseases slowly progressing, for in the former case we have in addition the element of shock in operation. But it will be observed also that even allowing for this, Flourens' incisions, while they were confined to the outer parts, caused very slight disturbance, and that it was only when the deeper parts were reached that the symptoms of want of coördination were well established. Consciousness was never lost during the operation, and intelligence remained unimpaired. It may be stated then—and this will be further illustrated in the consideration of the next question—that in a wound of the cerebellum the person injured need not necessarily fall, and that it would be possible for him to make forward movements for some distance, irregular it may be, but so long as the cerebral functions were not interfered with, with absolute consciousness and intelligence.

3. Is a wound of the cerebellum a necessarily fatal injury, immediate or remote? Any lesion of the brain substance is always dangerous, and may be attended with immediately fatal consequences. But, on the other hand, there are numerous instances on record in which the most severe injuries have been unattended with any symptoms. Professor Bigelow vouches for a case in which an iron bar, weighing 13½ lb., 3 ft. 7 in. long, and 1¼ in. in diameter, was driven through a man's skull by a blasting charge. It entered the cranium opposite the left angle of the lower jaw, behind the zygoma, and emerged on the left side of the centre of the frontal bone, near the saggital suture. The man was conveyed home in a cart, in which he sat upright, descended of his own accord, and then with but little help mounted a long flight of stairs leading to a piazza, where he sat down, perfectly conscious, until aid could be procured. He recovered.[7] A case more in point is that recorded by Brown-Séquard,[8] which is from notes supplied by Mr. Brownfield, house-surgeon to the Poplar Hospital. A man fell into the hold of a ship a distance of sixteen feet. He fell so that the back of his head struck against a railway bar. The immediate effect was a slight stunning, but so slight that he was able to walk out of the ship's hold on to the deck. The surgeon who saw him found no symptoms, and told him to go home and rest. He walked one-third of a mile to the hospital, and on admission walked upstairs to bed. He, however, died the same night. On post-mortem examination there was a blood effusion under the dura mater on the surface of the left hemisphere. It was traced forwards and downwards around the anterior lobe, and then backwards along the base of the skull to a laceration of the cerebellum. This laceration was of the left lobe, on the inferior and posterior surface. It was vertical, an inch and a half in length, and half an inch deep. It was situated in the lobe quite away from the pons or crus cerebelli. Other cases from the history of the American war show certainly that injury is not immediately fatal, and the case I have just cited proves that a very extensive lesion of the cerebellum may be present without giving any symptoms whatever of want of power of coördination.

[8] THE LANCET, Nov. 30th, 1861.

HOSPITAL DEMONSTRATION AT HAMPSTEAD.—A Friendly Societies' demonstration and church parade was held at Hampstead on the 24th inst. on behalf of the North London Hospital for Consumption. On the route of march to the parish church, where a specially arranged service was held, tables and collecting boxes were placed at convenient points, and a liberal collection was made at the church.

CYSTINE IN THE URINE SUCCESSFULLY TREATED BY LARGE DOSES OF CARBONATE OF AMMONIA.

BY LIONEL S. BEALE, M.B., F.R.S.,
PROFESSOR OF MEDICINE IN KING'S COLLEGE, AND PHYSICIAN TO KING'S COLLEGE HOSPITAL.

CYSTINE is one of the most persistent of urinary deposits. After it has once appeared it may be produced, and in considerable quantity, over a period of twenty years or more, or its production may only cease with life. It is among the least common of urinary deposits, and usually its presence is not associated with any symptoms more serious or definite than malaise, a feeling of weakness, fatigue, or exhaustion, with depressed or very low spirits. One of the most remarkable cases of cystine deposit which I ever saw came under my notice many years ago, and has been under observation for fifteen years or more. During part of this time I saw the patient very frequently, and made many examinations of the urine, of the deposit, and of the calculi, which he passed in considerable numbers.

The patient (E. H. O——) was a fairly healthy-looking man, of thirty, 5 ft. 5½ in. in height, weighing 9 st. 6 lb., who was by trade a packer, an occupation involving pretty hard work and long hours. For four years before he came to me he had suffered more or less from lumbar pain and discomfort about the thighs, especially on exertion, and he often felt weak and low. He sometimes had to walk with a stick and had had to give up work now and then for a week or two at a time. About two years after the first commencement of the symptoms he suffered from a fixed pain in the left groin, and soon afterwards several stones were passed, sometimes to the number of twelve or more at once. One of the calculi, however, was so large that it remained in the bladder, and Mr. Coulson had to crush it.

I put the patient on carbonate of ammonia and told him to increase the dose gradually until it amounted to about fifty grains a day. He found the remedy agree with him so well that he soon exceeded this quantity, and for twelve months he took as much as fifty-five grains daily on the average, on some days consuming much more, on others considerably less, than this amount. In this time he did not pass as many calculi as before he had passed in a single month, and his weight increased to 9 st. 11 lb. In the next year he took about thirty-five grains of carbonate of ammonia per diem, and in the following only an average of about twenty grains a day. This patient's family history was not very satisfactory. His mother died at the age of fifty-two of phthisis, and two sisters died under the age of twenty-five of the same disease. He did not look a strong man, and the muscles of his arms and legs were below the average size and prominence. When a young man he used to take violent exercise and rowed in races. The quantity of urine passed was generally about the average, and never exceeded three pints. Every specimen that passed during a period extending over at least five years, he feels sure contained cystine. Afterwards the cystine was very frequently detected in considerable quantity. The crystals could be seen in the urine immediately after it was passed as small sparkling grains. The ammonia not only diminished the formation of the cystine, but the patient found that while he was taking it his bowels acted freely and he never required an aperient, although previously he had been much troubled by obstinate constipation. When the ammonia was not taken he says he did not feel as well as when he was taking it. He found no inconvenience from taking these large doses of carbonate of ammonia, and soon became so accustomed to the taste that he did not object to it in the least. I have seen this patient at intervals during the last few years, and although cystine in small quantities was generally present in the urine, it gave him no inconvenience, and no calculi seem to have been formed for the last three or four years. In this case, then, cystine has been found in large or small quantity during a period of at least eighteen years, and for the first five or six years of this time hundreds of cystine calculi were passed, the largest being about three-eighths of an inch in diameter, the smallest not larger than the head of a very small pin. The cystine crystals formed a visible whitish deposit, which varied much in quantity, even from day to day, but sometimes formed a sediment.

Digitized by Google

Another case was that of a gentleman about fifty, who had suffered from abundant cystine deposit for two years before I saw him, and had passed seven or eight renal calculi, some of them beautifully crystalline, and entirely composed of cystine. This patient took fifty grains of carbonate of ammonia dissolved in two ounces of distilled water three times a day after a meal for upwards of two years without any inconvenience, and during this time he had not even once required an aperient. If he gave up the ammonia he did not feel "up to the mark." As the amount of ammonia seemed very large in proportion to the water in which it was dissolved, I had twenty-five grains of Howard's volcanic carbonate of ammonia dissolved in an ounce of distilled water, and found that, although it tasted very strongly, it was not caustic. On inquiry, Mr. D—— informed me it was only gradually that he reached this degree of concentration, but that he experienced no difficulty in taking it. He took it immediately after a meal—"on an empty stomach it produced nausea." For three years, with scarcely an intermission, 1050 grains of carbonate of ammonia were taken per week. The cystine deposit ceased during the last year of taking the medicine, and three years have now passed without its recurrence. I think, therefore, we may regard this case as really "cured" by the large doses of carbonate of ammonia.

It is to be feared that the tendency in the present day is rather to prescribe new remedies which are being continually introduced than to select from old ones such as are known to have valuable properties, and which have been proved by long experience to be really beneficial in certain pathological conditions. Far from condemning the new because they are new, like all who know the extreme value of such things as salicylate of soda and bromide of potassium I am most anxious to acknowledge my gratitude to those who devote themselves to the study and the discovery of the healing properties of every substance that can possibly be of use in treatment. But, while I am desirous not to say anything that could suggest to the reader that I am condemning the new things, I would impress upon the rising generation of practitioners the importance of being careful not to neglect the old. One cannot but desire that a drug like ammonia, so valuable in many forms of disease and departures from the healthy state, should not be forgotten or laid aside. The cases of cystine deposit to which I have drawn attention prove not only that large quantities may be taken without detriment or inconvenience, but that the use of the drug may be continued for a considerable period of time with advantage, and without the slightest derangement of any of the physiological processes being occasioned.

In our endeavours to help those who have acquired the vicious habit of consuming too much alcohol, ammonia is of great use, but it ought to be given in doses far larger than those in which it is usually prescribed. One of my patients assured me that he found ammonia very beneficial, that it relieved him of the feeling of tiredness from which he frequently suffered, and enabled him to perform hard work without getting exhausted. Not only have I found great benefit result from giving ammonia in considerable doses in many low forms of illness, but I have experienced its good effects by taking it myself. It acts very differently from any form of alcohol, although its effect upon the patient as judged from his own sensations appears to be somewhat similar. Though no feeling of hilarity seems to be induced by it, the lowness and depression of spirits and the tired feeling affecting the muscles, or rather the nerves and nerve centres by which they are supplied, are often removed in the course of half an hour or less by a dose of ammonia.

The cases I have adduced are sufficient to show that ammonia may be given in much larger doses than are generally prescribed, and that it need not be diluted to the degree generally supposed to be necessary. We used to be taught that five grains of carbonate of ammonia should be dissolved in at least an ounce of water, but as one of my patients took as much as twenty-five grains per ounce, and continued this three times a day for three years, we may feel satisfied that a solution of from ten to fifteen grains per ounce may be taken without difficulty, and I have prescribed this as often as once an hour in cases where the heart's action was very feeble and a decided stimulant was evidently necessary.

The public have discovered the value of sal volatile in cases of [illegible] and many minor ailments, but ammonia, like many other [illegible] of real value in the treatment of many departures from the healthy state, has lately been somewhat neglected, and is, like some other valuable remedies, in danger of being forgotten amid the multitude of new preparations which thrust themselves upon our notice; and it is therefore desirable that attention should be directed to its usefulness, as well as to the value of many other drugs which have been of real service to past generations of patients.

Grosvenor-street, W.

ON FIVE CASES OF

SPORADIC CRETINISM IN SCOTLAND.

BY ROBERT KIRK, M.D., F.F.P.S. GLASG.,
OUT-DOOR PHYSICIAN-ACCOUCHEUR TO THE GLASGOW [illegible] INFIRMARY.

(*Concluded from page 316.*)

CASE 4.—J. R——, male, aged thirty years, born at Falkirk, where he still lives. His parents are both in good health, free from goitre, and state that they knew nothing of the malady until it appeared in three of their children; to be noticed presently. The history is in other respects like that of the others, except that the father has occasionally indulged in drink. The patient is the third of eleven children, eight of whom are quite healthy; his eldest sister, who died lately, was affected like himself; his youngest sister is the subject of Case 5. Nothing was thought to be wrong with any of these three at their birth: they were like other children. It would seem, however, that there were certain indications of the malady, although of a very different kind from those existing in the former cases; for the mother stated that J. R—— was an extremely beautiful infant, having a fine pink flush on his cheeks and ears like wax. After some time, although it was impossible to find out exactly when, he gradually changed; his complexion became dull and sallow; he grew slowly, and had a small appetite; years elapsed before he cut his first teeth; at seven he began to walk with a feeble and tottering step, and he was ten before he made the first feeble efforts to articulate. The neck is the only part of the body that has ever been swollen, where there is a bronchocele of considerable size. His height is 4 ft. 6 in.; circumference of the head 21½ in.; there is a considerable posterior curvature of the spine in the cervical region; the head, trunk, and limbs are fairly proportioned; except a slight doughiness of the ears, there is no sign of myxœdema about the skin; no swelling anywhere. On the contrary, he is emaciated, and the skin is soft and free from desquamation. He has a double goitre, the swelling being as large as the fist on the left side, and somewhat less on the right; there is no trace of supraclavicular swellings on either side of the neck. He has the following features of the cretinous type of conformation:—Wide interval between the eyes; root of the nose much depressed; alæ nasi very wide, and the point of the nose elevated; arch of the palate narrow and high; lower lip depending, markedly thick in comparison with the upper, which is thin; tongue thick but moist; tendency to salivation. He is beardless but the hair of the scalp is abundant; abdomen slightly tumid; genitals not examined, but I had the opportunity of observing that there was a fair amount of pubic hair. The skin is generally dry; there are numerous pink spots over it, somewhat like faint petechiæ, some of these being apparently older and fainter than the others; veins are everywhere noticeable over the surface. He has his permanent teeth, and the lower incisors are notched as in Case 3; the upper are much worn. He is extremely slow in all his movements and cannot be hurried; he breathes heavily on the least exertion, from evident compression of the trachea; pulse and cardiac sounds weak; temperature in the axilla 97·8°; his skin always feels cold and he often becomes blue; he is extremely sensitive to cold, and last winter his mother says he was on one occasion nearly frozen to death. His articulation is hurried and indistinct, and seems almost painful to him; it is perhaps not so nasal as in other cases, but I heard only a few words, thrown out with a jerky effort. He could never be taught to read, write, or do any sort of work. All his senses are good, and he has no perverted idiotic propensities. His mother says the goitre is growing faster of late, and he is getting gradually weaker. The eldest sister of this patient was in a rather worse condition than himself, and was at

Digitized by Google

one time, apparently, swollen; she had a bronchocele on the right side as large as a two-pint pitcher. She died at the age of thirty-two of dyspnœa with gradually increasing emaciation, stiffness, and feebleness. She was about the size of a girl of twelve years.

CASE 5.—A. R——, aged fourteen, sister of the foregoing, and youngest of the family, is 4 ft. in height. She does not present so bad a case; the limbs are fairly proportioned, but the hands and wrists are thick; the fingers are tolerably long; the abdomen is slightly tumid. She can walk well; though weak on her legs and not so forward as girls of her age, she has made some progress with her education. Nevertheless, she is a decided cretin. There is marked flattening of the nose, with elevation of the point, and very wide alæ nasi; wide interval between the eyes; both lips thick, especially the lower, the face having a prognathous appearance; tongue moist but thick, and too large for the mouth, while its movements are precisely the same as those seen in adult myxœdema; palate vaulted; intensely nasal intonation. The neck is remarkably broad at the base, although not in the least myxœdematous; there is a goitre on the right side, about the size of an egg; no trace of swellings above the clavicles. Skin generally dry and cool, and nowhere rough; no desquamation; upper eyelids slightly tumid, forming slight folds, which rest nearly on the eyelashes; ears a delicate pink, showing fine veins behind. Permanent teeth developed, and the lower incisors are notched, as in Cases 3 and 4. The upper incisors require special notice. These are quite normal in front, but the posterior surface is excavated into a hollow having two sides, united at nearly a right angle. One of these sides is horizontal, and nearly on a level with the gum; the other forms the posterior surface of the tooth. This latter side is marked by three distinct black lines, radiating from the bottom of the cavity. These features are most pronounced in the central pair, the lower half of which is thus very thin. They have none of the marks of syphilitic teeth. I examined the teeth of both parents, and of their eldest son and two daughters, and found them excellent; none of them being syphilitic, nor having any of the characters above described. The patient is always cold, and fond of sitting by the fire; temperature 98°; she sometimes sweats a little. Her heart and pulse are tolerably strong, but her mother thinks she is becoming weaker of late, especially in walking. These three members of the family have never had scarlatina, measles, or whooping-cough.

Remarks.—I do not find in the latest French treatises on cretinism — as for instance, Baillarger's "Enquête sur le Goitre et le Crétinisme" (1873), or the article in the "Dictionnaire des Sciences Médicales" (1879)—any reference to the characters of the upper incisors I have just mentioned. I would draw special attention to them; they are very distinctive, and should they be found constant might be of some diagnostic value. It is true there are numerous cases where this will not be available, for many cretins never get the second teeth, and when these do appear they are very carious and are soon lost. But where they exist this point should be attended to, and might be found of service in thoses cases, of which a few have been recorded, where myxœdematous symptoms supervene in childhood after the second dentition, and in which it is difficult to determine between myxœdema and congenital cretinism.

It cannot be doubted that the above cases are all examples of cretinism. Cases 3 and 5, which present the malady in its slighter forms, have a considerable number of marks which belong only to this disease, and which certainly differentiate them from the subjects of any other cachexia. This being granted, there is one point which appears very striking. While all have something in common there is a wide divergence between them in many respects. The same seems to be the case, too, with endemic cretinism, for we meet with descriptions of cases which are evidently the exact counterparts of the above, and even others besides. Yet we scarcely find any attempt made at classification, except with reference to the different degrees of severity of the symptoms. One might suppose that cretins ought to be divided into classes founded on well-defined differences of morphological type, with divergence in symptoms, history, and other particulars. Amongst many other features which seem to characterise one class more than another, we find, for instance, a remarkable difference with respect to myxœdema, some being even thin, while others are much swollen. In the light of recent researches can we doubt that this alone is an important distinction, probably having reference to various conditions of the thyroid, and that these two classes of cases will show characteristic discrepancies in a variety of other points, as in the cases above detailed?

These cases, further, have an important bearing on certain views which have been lately entertained as to the supposed difference between endemic and sporadic cretinism. Mr. Curling, as is well-known, in a post-mortem examination of two cases of the latter found that the thyroid was absent and that the supra-clavicular swellings were composed of fat, and the late Dr. Fagge formed the opinion that these two features constituted an anatomical distinction between this affection and endemic cretinism, and he published four additional cases in which during life the thyroid seemed also to be absent. Subsequently, however, he had the opportunity of making an autopsy of one of his own cases, and he found that the thyroid was not only present, but was goitrous in its right lobe. He duly emphasised this fact, but still believed that the fatty tumours remained as a constant distinction between the two diseases, having been found in all cases of sporadic cretinism, even in those accompanied with goitre, of which two had been reported at that date—namely, Dr. Fagge's own case just mentioned, and one reported in the *Medical Times and Gazette* for 1855 (vol. ii. p. 266). But the present series of cases clearly shows that this distinction was not founded on a sufficient basis of fact. Besides, are we sure that the thyroid is never absent, and the tumours in question never to be found, in endemic cretinism? After a careful search I have found no positive statements with regard to the thyroid in French authors, except as to the presence or absence of bronchocele; indeed, this was all that was proposed to be kept in view when the French Commission, of which Baillarger gives the report, was instituted. Again, in the article on Cretinism in the "Dictionnaire des Sciences Médicales" (1879), it is stated that the greater number of autopsies which have been made of cretins are untrustworthy, and we find no reference made to the neck except when goitre existed. We may suppose it possible that the point has been wholly overlooked. It would appear very probable that in some of the non-goitrous cretins, who are generally of the lowest type and correspond closely to the majority of cases of sporadic cretinism reported in this country, the thyroid will sometimes be absent. With regard to the fatty tumours, we have positive evidence that they were noticed by some observers. Thus M'Lelland, in his "Medical Topography of Bengal," states that the swelling in the necks of cretins does not always begin in the thyroid gland, but may commence with "a fulness of the base of the neck on one or both sides above the clavicles." If we do not find these mentioned in descriptions of endemic cretinism in France, neither do we find them referred to in cases of the sporadic affection in the same country until quite recently. In a case of sporadic myxœdematous cretinism in *Le Progrès Médical* for 1880, p. 709, by Bourneville, they are expressly mentioned, but in otherwise precisely similar cases reported in France ten years ago we find no reference to them. It is probable that they are in proportion to the myxœdematous condition generally, and are to be found in many cases of endemic as of sporadic cretinism.

But probably the chief interest of the preceding cases will be found to lie in the light they may shed on the question of the relationship of cretinism to the cretinoid affection or myxœdema of adults. The subject can only be glanced at within the limits of this article. How far are these two conditions related to each other? If we confine our attention to the first two cases, it would appear that we might fairly designate them as examples of congenital myxœdema. They closely resemble the adult affection in all essential points, with only such modifications in Case 1 as might plausibly be accounted for by the period of life at which the disease existed; although it is certainly curious that Case 2 should rather correspond to myxœdema at a very advanced age. But if affinity in essential features be granted, the question arises, Is myxœdema the principal factor in producing the various symptoms of cretinism, as has been suggested, and as it has been held to do in the adult affection also? The answer would seem to be in the negative. Case 2 belongs to a rather lower type than Case 1; the mental and muscular powers are weaker, while the deposition of mucin in the tissues, if such there be in this case, must be very much less. It might be compared, perhaps, to Dr. Goodhart's case of myxœdema, in which little mucin was found in the tissues after death, and appears to teach the same lesson. If we go a step further, and admit that the remain-

Digitized by Google

ing three cases have anything in common with myxœdema, we must widen our range of view still more; and there would appear to be an intimate bond of connexion between the two. In Case 3 the ears, the cheeks, the thick lips (which, in framing themselves, to speak more especially, at once reminded one of myxœdema), and the furfuraceous desquamation, were all distinctive. In Case 5 the size and movements of the tongue and many other features could not be referred to any other cachexia. It is probable, too, that Case 4 was at one time more swollen than he is now, though in many points he still resembles a case of myxœdema; while in all there were marked nasal intonation, slow movement, defective mental capacity, susceptibility to cold, and other symptoms. It is evident that these symptoms were far from being in proportion to the apparent degree of myxœdema, neither did they correspond in gravity to the lowness of the bodily type of conformation as much as might have been expected. It is certainly curious, too, that the various features of myxœdema should crop up in such a variety of modified forms in these several cases, and that such characteristic phenomena as the furfuraceous desquamation should be present in one case and absent in others. The nasal intonation and the peculiarities of nasal conformation were more nearly alike in all than any other features. It might almost be said that the myxœdema of adults is but a single and stereotyped form of a disease which admits of numerous modifications, only to be found and studied in cretinism. The entire subject abounds in paradoxes. The apparent connexion of cretinism with goitre, on the one hand, and yet the existence of facts which have suggested an antagonism between the two on the other; the greater liability of females to the former and of males to the latter disease; the special susceptibility of women to goitre at the climacteric period of life and after confinement,[1] and to atrophy of the thyroid and myxœdema in the same circumstances—these are all facts probably connected by some yet hidden and secret links.

Partick, Glasgow.

ACUTE INTUSSUSCEPTION IN AN INFANT EIGHTEEN WEEKS OLD.

STERCORACEOUS VOMITING; INFLATION BY WATER PER ANUM; RAPID SUBSIDENCE OF SERIOUS SYMPTOMS; RECOVERY.

BY HERBERT COLLIER, M.D. BRUX., &c.

WILLIAM B——, aged eighteen weeks, was brought under my notice on Feb. 16th last, suffering from great collapse, and with marked signs of acute obstruction of the bowels. The mother stated that she suckled the child from birth, but as she did not have sufficient milk she supplemented this diet with small quantities of bread soaked in water and sweetened with sugar. The infant had never rejected his food till about a week previous to my seeing him, when he commenced to return a small portion of the milk after each meal; the bowels also became costive, and the evacuations alimy and highly offensive. The child, however, "appeared quite well, and seemed more hungry every day." At the age of ten weeks he had a slight attack of bronchitis, which, under medical treatment, passed off in a few days. Since his recovery no medicines of any kind had been given. On Feb. 15th, whilst lying asleep in his mother's arms, he suddenly became convulsed and appeared in great pain, screaming loudly and struggling, so that it was with difficulty that he could be held. After the fit had lasted a few minutes the struggling gave place to violent straining, "as if he was trying to relieve himself," and during these efforts a large quantity of gas was discharged per anum. On the diaper being inspected, it was found to be soaked with bright blood and slime, but did not contain any fæcal matter. He now appeared more calm, and after a short time took the breast, but almost immediately afterwards became very sick, bringing up a large quantity of milky fluid. Since then he had mostly been quiet, crying and straining only by "fits and starts." He had taken small quantities of milk-and-water from a teaspoon, but nearly always returned them immediately. No natural action of the bowels had occurred since an hour before the onset of the attack, although the diapers were several times found stained with "bright watery blood." Urine was passed more frequently, but in smaller quantities than usual.

When seen by me on Feb. 16th, at 4 P.M., I found the condition of the child to be as follows. He was well nourished, but much collapsed, with pale face and pinched, drawn features; pulse 100, feeble and irregular; respiration 30, shallow; skin cold and perspiring; temperature 100·5°, taken in the rectum. There was much distension of the abdomen, and percussion yielded a tympanitic note, except where the right inguinal and hypogastric regions were occupied by an elongated swelling, which ran in a direction upwards and inwards, and could plainly be seen and felt. Pressure over this tumour gave rise to crying and struggling on the part of the infant. On account of his tender age it was not considered advisable to extend the examination to an exploration of the rectum. Three blood-soiled diapers were shown by the mother, and one of them, said to be in use at the onset of the attack, contained about two ounces of blood and mucus. Having diagnosed acute intussusception, it was thought best to resort to inflation of the bowels as soon as possible, but as an anæsthetic was necessary for the more perfect execution of this operation, some valuable time was lost in procuring the requisite assistance. In the meanwhile hot fomentations were applied to the abdomen, and a mixture containing tincture of belladonna, chloric ether, and sal volatile, in appropriate doses, was prescribed every two hours. At 6 P.M. the child was in much the same condition. The pulse was slightly stronger, and he had not vomited since my last visit. He had refused the breast, but had taken and retained two doses of the medicine. The same treatment was continued, in addition to which ten drops of brandy in a teaspoonful of ice-water were given every half hour. At 8 P.M. the pulse was still more improved, although vomiting had occurred twice since I last saw him. About an ounce of blood-stained mucus was passed per anum during this visit. The treatment was continued. At 9 P.M., after a consultation with my friend Mr. Blake of Great Yarmouth (to whom I am indebted for kind assistance during the subsequent inflation of the bowels as well as for giving chloroform), it was decided to anæsthetise and attempt to dislodge the prolapsed portion of bowel by injecting water. After chloroform had been inhaled some few seconds, and before insensibility was produced, the patient became violently sick, ejecting about half a pint of pale-yellow fluid, having a strong fæcal odour. The pulse at this moment became scarcely perceptible, and the child appeared in the gravest danger; but on chloroform being suspended and ammonia applied to the nostrils, the pulse returned, and remained fairly strong throughout the remaining stages of anæsthesia. The fingers of one hand being kept in contact with the sausage-shaped tumour described above, warm water was slowly injected into the rectum by means of a Higginson's enema syringe, care being taken to prevent its return by the side of the nozzle. When about twenty ounces had been injected, a sense of the tumour slipping away was plainly perceptible to the fingers in contact with the abdomen. By the time some thirty-five to forty ounces had been injected the tumour had entirely disappeared, and the most careful examination failed to detect it. The patient was now wrapped in warm blankets, and the injected fluid allowed to drain off. During returning consciousness the child once more vomited freely, bringing up fluid of the same colour, and possessing the same strong fæcal odour, as before. Ten drops of brandy in a teaspoonful of ice-cold water were subsequently administered and retained, and the child afterwards manifested an inclination to sleep. The hot fomentations were again ordered to be applied to the abdomen, and the belladonna mixture to be given every two hours. At 12 P.M. a large quantity of water was found to have been passed per anum. The child appeared more comfortable, and was sleeping calmly. He had not evinced a desire for milk when placed to the breast. On the diapers being changed in my presence, about two tablespoonfuls of dark-yellow fæcal matter were found to have been passed. The fomentations were ordered to be continued to the abdomen, and the mixture given every four hours.

Feb. 17th.—9 A.M.: The child had taken the breast twice during the night, and had another natural action of the bowels at six o'clock this morning. From this time the patient made an uninterrupted recovery.

The features of interest in this case are so obvious that it

[1] Baillarger, p. 18.

Digitized by Google

is unnecessary to particularise them. I may, however, be permitted to state that, so far as I am able to ascertain by reference to several authors upon the subject, it affords the earliest example of recovery in so young a victim to this disease.

Nullas autem ostalia pro certo noscendi vias, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI, *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. THOMAS'S HOSPITAL.

TWO CASES OF DISEASE OF THE THYROID GLAND; REMOVAL OF ISTHMUS AND PART OF LATERAL LOBES; CURE; REMARKS.

[Under the care of Mr. SYDNEY JONES.]

FOR the following notes we are indebted to Mr. W. H. Battle, surgical registrar.

CASE 1.—E. H——, aged twenty-four, married, and having one child, was admitted on Jan. 23rd last. The patient had not suffered from any previous illness, excepting periodical severe frontal headache, accompanied by nausea. When she was eight years old a swelling was first noticed in the neck, and thenceforward it steadily increased in size. For the last ten years it had at times caused difficulty in breathing. During the attacks of dyspnœa the respiration was noisy but there was not any lividity of the face or lips. Each attack generally lasted a few hours, but once it continued for three days. During the last two years there had occasionally been difficulty in swallowing, and for about the same period of time there had been palpitation of the heart, and "faint sickness" at the catamenial periods. For the last six months the difficulty in swallowing had been more frequent, and she stated that she had been getting paler.

On admission, she was a pale but well-nourished woman, of rather dark complexion, holding her head down a little on the right side. She complained of a throbbing swelling in front of the neck, and attacks of difficult breathing, coming on once or twice a week. There was a tumour in the position of the thyroid gland, moving upwards when the patient swallowed. Examination showed it to consist of two divisions, somewhat egg-shaped, the larger being situated under the right sterno-mastoid, and the smaller in the middle line of the neck, and connected with the larger by means of a broad isthmus. In the middle line the tumour extended from the cricoid cartilage to the sternal notch, its vertical measurement being 2½ in. On the right side the tumour passed under the sterno-mastoid, which it pushed forwards, and reached from the point where the external jugular vein crosses the posterior border of the muscle to the clavicle. This lateral portion of the tumour was softened, and there was more pulsation visible over it than over the median line (communicated by the carotid). There was no fluctuation anywhere. The vertical measurement of the right lobe was 3½ in., widest transverse measurement 5½ in. The enlargement of the left lobe was comparatively slight, excepting near the isthmus; it, however, extended from the right of the middle line to underneath the anterior margin of the sterno-mastoid. The superficial veins were not enlarged, and there was no exophthalmos. Temperature normal. Further examinations made during the time intervening between her admission and the operation (fifteen days) proved absence of cardiac and renal disease. There was no venous murmur in the neck, the breathing became easier, and she had no attack of dyspnœa, but complained of occasional difficulty in swallowing and of palpitation. The catamenia were regular, and there was no increased difficulty in respiration at the period. A tender spot was found on the left side of the tumour under the sterno-mastoid, over a part which felt firmer than the surrounding substance.

On February 6th, the patient having been placed under the influence of chloroform, Mr. Sydney Jones made an incision in the middle line from the upper border of the tumour downwards to the episternal notch. When the deep fascia was divided, the tumour, covered with its capsule, bulged forwards through the incision; the isthmus was at once seen to the right of the middle line, and it became more evident that the bulging in the middle line was due to a displacement of the left lobe of the gland. There were only two or three vessels of any size which required to be ligatured. The finger was passed behind the isthmus from below; and, with this as a guide, an aneurysm needle, carrying a double ligature of strong silk, was passed through the middle of the left side of the isthmus, the ligatures being locked and tied above and below. A similar double ligature was passed on the right side and tied; the isthmus was then divided with the scalpel. A double ligature was then passed through part of the left lobe so as to include about the mesial third, and the portion internal to the ligatures was cut off. The section exposed semi-translucent whitish matter scattered thickly through the substance of the gland. A few small vessels required to be ligatured in the wound, but there was no hæmorrhage from the cut surface of the gland.

An examination of the trachea proved it to be keel-shaped and compressed laterally, the sharp edge pointing forwards; it was also displaced to the right. The ends of the strong silk ligatures were left long and tied in a knot outside the lower angle of the wound, from which a drainage-tube passed the whole length along the floor to the upper margin. Alternate silk and catgut sutures were used to close the wound. Carbolised oil, iodoform wool and salicylate wool, secured by means of antiseptic gauze bandages, were applied as dressing, and the patient placed in bed, sand-bags being used to keep the head steady. In the evening the wound was redressed; there was slight venous oozing and the temperature was 97·4°. On the 7th the wound was again dressed; the discharge was blood-stained; there was also a quantity of clear unstained serous-looking fluid. The head and shoulders of the patient were raised, to permit of free discharge. Temperature, morning, 102°; evening, 102·8°. On the 8th the pulse was 92; respiration 24; temperature, morning, 101·2°; evening, 100·8°. On the 11th the remaining sutures were removed, the wound having quite united. On the 16th a lotion of chlorinated soda was applied and strapping was placed across the wound. On the 29th a lotion of sulphate of copper (two grains to the ounce) was applied, and on March 4th the patient was allowed to get up, but it was not until nine days later (thirty-fifth after the operation) that the last ligature came away, after which the wound soon closed. She left the hospital on March 16th.

After February 17th the temperature did not reach 99·6°; between the 8th and the 17th the morning temperature varied from 99·2° on the 15th to 101·4° on the 12th, and that of the evening from 100° on the 10th to 102·4° on the 13th, there being an average difference of one degree between them during that period.

CASE 2.—H. K——, aged seventeen, a fitter, was admitted on March 24th. The mother of the patient had, it was said, a swelling in the neck similar to the patient's, but nothing definite could be discovered about it. In the present case the enlargement was first noticed in the lower part of the neck six months before admission. It slowly increased, but for three weeks had grown more rapidly, especially on the left side. Some alteration in the voice had been noticed for about four months; there had also been slight difficulty in swallowing. During the whole time since the commencement of the enlargement he had had aching pains in the eyes, and he has also had slight palpitation on unusual exertion.

On admission, there was considerable enlargement of the thyroid gland, extending from the level of the hyoid bone to the root of the neck, the greatest prominence being at the level of the isthmus, which, however, did not appear to be affected. The swelling was limited to the lateral lobes; it was soft but without fluctuation; there was slight pulsation to be felt. There was no fulness of the superficial veins. There was some cardiac hypertrophy, and a lengthening of the first sound at the base. No exophthalmos; no evidence of visceral disease. The circumference of the neck on a level with the seventh cervical vertebra was fifteen inches, round the root of the neck fifteen inches and a half, being a quarter of an inch more on the left than on the right side.

On April 2nd, Mr. Sydney Jones operated, making an incision in the mid-line of the neck, about four and a half inches in length, down to the capsule of the thyroid isthmus, which was exposed. Some veins required ligature, and after they had been secured, the isthmus was isolated by means of the director; the isthmus, which was very friable, gave way

Digitized by Google

when it was being separated from the front of the trachea; a double silk ligature was then passed through the anterior part of the lateral lobes and tied in each case above and below, a considerable portion being thus removed. The substance of the gland was granular and easily broken down. The trachea had been slightly compressed laterally by the growth; its anterior surface was quite cleared by the operation. A drainage-tube was placed along the wound, the edges of which were brought together by means of silk sutures, the long ligatures of thick silk which were attached to the thyroid being brought out at the lower angle. The wound was dressed under the carbolic spray in the usual manner.

For some hours after the operation the patient had a headache, but otherwise felt quite well. The day after the operation the wound was redressed; six days later the sutures were removed, plaster being placed across the wound to keep the edges well apposed. Two days later chlorinated soda lotion was substituted for the antiseptic dressing and the drainage-tube removed, and twelve days after the operation the last ligatures came away. He got up on the sixteenth day, and twenty days after the operation the neck measured fourteen inches. When seen after he had left the hospital there had been further diminution in the size of the neck.

On the evening of the day of operation the temperature was 98·8°, rising next morning to 103·2°, falling during the day to 99°, and rising later to 101·8°. There was then a gradual fall (excepting on the 6th, when it rose to 102·2°) to 96·8° on the 9th; from that date until the morning of the 12th there was a gradual rise, reaching 103°, and falling next day to 96·4, after which it rose to normal, and continued so.

Remarks.—In the cases which have been operated on in the median line by Mr. Sydney Jones, in some a well-marked isthmus, drawing tightly together the lateral lobes, has been observed; in others the isthmus has not been so well marked. In all cases the object aimed at has been to form a deep sulcus in front of the trachea so as to make a wide separation between the lateral lobes, and to effect this wide separation when the isthmus has not been well marked, and when the lateral lobes have been approximated part of each lateral lobe has been removed after transfixion with a double ligature. In all cases shrinking of the lateral lobes has occurred, in addition to the relief to the difficulty of breathing and deglutition. Free drainage has been secured in the middle line by a drainage-tube in front of the trachea, and no symptoms causing any anxiety have occurred.

LIVERPOOL NORTHERN HOSPITAL.

ANEURYSM OF ARCH OF AORTA; EMBOLISM OF ABDOMINAL AORTA; NECROPSY; REMARKS.

(Under the care of Dr. DICKINSON.)

FOR the following notes we are indebted to Mr. S. W. Roughton, M.B.Lond., house physician:—

A. H——, a sailor, aged twenty-eight, was admitted into the hospital on March 29th of the present year. He stated that for four weeks he had suffered from pains in his joints and across the front of his chest. On examination, no physical sign of disease was discovered. The urine was natural. He denied ever having had any venereal disease, and said that he had always been temperate. The pains in the joints subsided in a few days, but the pain in the chest persisted and became worse. On April 12th he first complained of slight cough, and on April 16th an area of dulness over the upper part of the sternum, continuous with the cardiac dulness, was first noticed. Over this dull area the heart sounds were very loud, but no bruit was audible; the right radial pulse was also noticed to be a little smaller than the left. He was ordered ten grains of iodide of potassium three times a day. On April 20th, distinct pulsation could be felt over the upper part of the sternum and costal cartilages on the right side. A bruit was also audible at the right second intercostal space and conducted into the subclavian. A sphygmographic tracing showed a curve with rather slow ascent and a well-marked round top; this was more apparent in the tracing given by the right radial artery. On May 22nd the patient was put upon Tufnell's treatment. At first he behaved very well, and at the end of a week the bruit was a little softer and the pain not so severe. The pulse, however, always remained rather rapid, varying from 90 to 110 per minute. About June 17th the patient began to complain that he could only lie upon his right side, for if he turned upon his back his breathing became much impeded, and he began to cough. By June 23rd he had become tired of lying still, and insisted upon sitting up in bed. His face soon became slightly blue and œdematous, and the veins of the neck were a little distended. All these symptoms gradually increased, the pain in the chest becoming so severe that he could not sleep without morphia.

On July 9th he was feeling rather easier than usual, but at noon he was suddenly seized with violent pain in the abdomen, became greatly collapsed, and bathed in a cold perspiration. He complained of numbness in his legs, and of inability to move them. No pulsation could be felt in either femoral artery, and both legs were cold and livid. At 6 o'clock the same evening he spat up some blood and gradually sank, death occurring at 10.30 P.M.

Necropsy.—Immediately above the attachment of the aortic valves the aorta was dilated, forming a large, irregular, but more or less spherical cavity, about the size of a fœtal head. The aneurysm involved the whole of the circumference of the artery from its origin to the beginning of the descending portion. Its walls were very thin, and very little laminated clot was found adherent to them; but the cavity contained a large quantity of soft, dark clot in places indistinctly laminated. The remainder of the aorta was fairly healthy, but was completely filled by a soft dark clot terminating at the bifurcation of the aorta. On cutting into the clot, no portion of different consistence was found in its interior, the whole clot resembled very closely that found in the aneurysm. Besides some hæmorrhage into the substance of the left lung, there was no other pathological change.

Remarks.—The chief points of interest in this case are:—(*a*) The absence of any discoverable cause, and the age of the patient—viz., twenty-eight years; (*b*) the gradual appearance of the symptoms made the case very interesting to watch clinically; (*c*) the failure of the method of treatment employed was no doubt mainly due to the aneurysm involving the whole circumference of the aorta, and thus being very badly suited to the deposition of laminated fibrin; (*d*) the immediate cause of death was, no doubt, the detachment of a portion of the soft clot contained in the aneurysm and its impaction in the bifurcation of the aorta, followed by secondary thrombosis filling nearly the whole vessel.

CUMBERLAND INFIRMARY, CARLISLE.

LARGE IRREDUCIBLE UMBILICAL EPIPLOCELE; REMOVAL OF OMENTUM, SAC, AND REDUNDANT SKIN; WOOD-WOOL DRESSING; RECOVERY; REMARKS.

(Under the care of Dr. LEDIARD.)

THE patient, a married woman, first applied at the out-patient room with an umbilical hernia of large size, containing omentum and bowel, the latter only being reducible. The tumour had gradually increased in size since the date of origin—viz., six years previously. As the patient was seven months pregnant she was advised to return after her confinement, which she did upon July 9th, 1884. The pyriform tumour was central and about the size of a fist.

On July 14th an incision was made over the hernia; the sac opened, and the few adhesions which united the omentum to it were broken down. The omentum was then ligatured and cut away and the pedicle secured by catgut stitches to the margins of the ring; the sac was next separated from the cellular tissue and cut away, and the skin was also freely cut away so that a few stitches brought the edges together neatly over. A drainage-tube and some wood-wool was the only dressing used. The wound healed in two weeks.

Remarks by Dr. LEDIARD.—This is the fourth case of hernia treated in nearly the same manner. Two cases were small femoral ruptures, the sacs of which contained irreducible bits of omentum, and upon which the pressure of a truss was unbearable. The other case was an inguinal hernia the size of a duck's egg, containing adherent omentum. In each instance the sac was cut away, ligatured, and stitched to the margins of the ring. In all good recoveries were made, and the dressings were strictly antiseptic. It is especially desirable to obtain a radical cure in umbilical hernia, on account of the increasing disability they seem to cause, and not disability only, for sooner or later they generally become a positive source of danger. The patient whose case I have given was but twenty-nine years of age, and future pregnancies may imperil the lasting success of the treatment. When the history of the rise and progress

Digitized by Google

of Listerism comes to be written one, by no means the least important, of the gains to be recorded will be the dating of the performance of operations which were formerly considered either impracticable or dangerous, and amongst these I venture to place herniæ of all kinds, for in the future we shall hear more of the knife and the needle than the truss in the treatment of this class of ailments.

Reviews and Notices of Books.

Compendium der Pathologisch Anatomischen Diagnostik. Von Dr. JOHANNES ORTH. Dritte Auflage. (A Compend of Diagnosis in Pathological Anatomy. By Dr. JOHANNES ORTH. Third Edition.) Berlin: A. Hirschwald. 1884.

THE first edition of this useful work is known to English readers in the translation (New York: Hurd and Houghton) of Drs. Shattuck and Sabine; but so numerous have been the additions and so careful the revision that this third edition is practically a new work. Dr. Orth, who is Professor of Pathology at Göttingen, has made many contributions to the subject, and is at present engaged upon a handbook which promises to take a prominent place in the literature of this subject. The plan of the present work is that of a guide to the post-mortem room. It opens with general directions for the performance of post-mortem examinations and microscopical investigation, and then deals in turn with the external appearances of the body, cutaneous and subcutaneous lesions, before treating of the internal organs. The description of these latter is taken systematically with reference to the cavities of the body, the spinal canal and the cranium, the thoracic and abdominal cavities; and lastly the extremity is considered. Directions are given for the examination of all these parts before the detailed systematic description of the morbid anatomy of the various organs is entered upon. As an example of the method pursued may be cited the chapters dealing with the lungs. The lesions of the pulmonary pleura are first described, and the external characters of the lung as regards size, form, colour, and consistence. The method of incising the lung and the general characters of the exposed surfaces follow, with directions for microscopical examination of the fresh organ. The author then describes in turn the diseased conditions, commencing with disorders of circulation—hyperæmia, hæmorrhage, infarction—distinguishing with Rindfleisch between the "simple" infarction from rupture of vessels, and the "embolic," which leads to mention of metastatic suppuration and fat embolism. Pulmonary œdema closes this section. The varieties of pneumonia are fully described—fibrinous, catarrhal, suppurating, and caseous. As to caseous pneumonia, he distinguishes three main forms—caseous bronchitis or bronchiolitis, pneumonia proper, and caseous peribronchitis; holding apparently to the view that tubercle is a secondary event in these conditions. Under the head of "productive" inflammation is described cirrhosis of the lung in its various degrees. Specific inflammations follow, the chief being tuberculosis, which is described in the disseminated form, in the acute partially disseminated, and in the infiltrating or pneumonic form. He explains that the distinction of these varieties is arbitrary, and employed only for the sake of facilitating description, for he admits that they are one and all the result of the same virus, the "bacillus Kochii"; and he shows that all depends upon the sense in which the term "tubercle" is applied. Tumours of the lung, atrophic and degenerative changes (including emphysema), are next dealt with, which enables him to dwell at greater length upon the distinctive lesions of phthisis. The chapter closes with abnormalities in the amount of air (atelectasis) in the lung, foreign bodies (pneumono-koniosis) and parasites. A comparison with the former edition shows here, as in other chapters, how widely the author has departed from the arrangement there adopted, with the effect of rendering his descriptions more comprehensive and exact.

Post-Nasal Catarrh. By EDWARD WOAKES, M.D. Lond. London: H. K. Lewis, Gower-street. 1884.

THIS work is the first volume of the third edition of "Deafness, Giddiness, and Noises in the Head"; it treats not only of post-nasal catarrh, but also of the various diseases of the nose causing deafness. The author has taken great pains throughout this volume to establish a physiological theory, on the full understanding of which he attempts to explain all the phenomena met with in the region to which he has devoted so much labour and attention. Every theory or principle which may be held by any physician or surgeon is unquestionably open to attack, generally from more points than one. We do not care in this place to enter into an elaborate discussion of the *pros* and *cons* of Dr. Woakes' hypothesis, but we may state that his principle of reflex nervous action in the sympathetic nervous system may fairly be accepted as a tenable position, which, if perhaps taken up somewhat too positively by its promoter, will nevertheless stand many of the tests of a scientific examination. The brief chapter on chronic or post-nasal catarrh and its sequences is a graphic description of the symptoms from which the patient suffers, as anyone who has the misfortune to know from personal experience will testify. The section on the hygienic management of the catarrhally predisposed is one with which we find ourselves in almost complete accord. The author is in his element in treating of the diagnosis of chronic catarrh by the aid of the various appliances and methods of examining the fauces, nose, and post-nasal space. Fig. 4 however, does not convey much information to our minds of the normal appearance of the fauces. The pathology and treatment of acute catarrh are briefly but ably dealt with. The various forms of chronic pharyngitis are all considered, and taught as modifications of one and the same process. The chief varieties discussed are the chronic hypertrophic catarrh of the naso-pharynx, follicular hypertrophic catarrh of the pharynx, or follicular pharyngitis, and chronic atrophic catarrh of the naso-pharynx, or pharyngitis sicca. Chapter IX. is concerned with simple hypertrophy of the pharyngeal tonsil; and the opinion that "although it is possible to effect some slight subsidence in the enlargement of the pharyngeal tonsil by the repeated application of such styptics as nitrate of silver &c., this method of treatment gives only a partial result, and requires a long period to accomplish even this. Evulsion of the mass is the only measure in which confidence can be placed." Lymphoid papillomata of the naso-pharynx form the subject of a lengthy chapter, which deals with their etiology, pathology, and diagnosis in an able, and with their treatment in a practical, manner. Stenosis of the nasal fossæ is considered as resulting from (1) diseases originating in connexion with the turbinate bones, and (2) diseases originating in connexion with the nasal septum. Considerable space is occupied with the pathology and treatment of the various affections blocking the nasal passages. Taken in every way, this excellent manual is well fitted as a guide to the student of the subject of which it treats.

OUR LIBRARY TABLE.

The Asclepiad. Vol. I., Nos. 2 and 3. London: Eade and Caulfield.—This quarterly periodical is solely the production of Dr. B. W. Richardson, and evinces, it need not be said, considerable labour as well as ability; we wonder what fractional part of the author's labours these volumes alone represent. Dr. Richardson succeeds in making the material at his command both instructive and

Digitized by Google

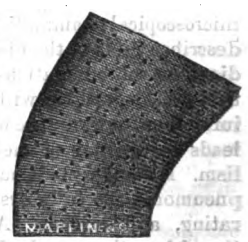
interesting. We were much pleased with the articles on John Keats (with original portrait on steel), and William Gilbert, M.D. (with portrait and three illustrations). To the Useful Notes for Busy Practitioners, we have on several occasions referred elsewhere. There is a great deal of truth in the chapter on the Folly of Scepticism in Remedial Art, though we should not be disposed to grant the writer all his propositions. Upper London, a project for radical reconstruction, was an amusing address delivered before the Society of Arts. The even level of the roofs of the houses in that part of Regent-street known as the Crescent is certainly favourable to the suggestion of an Upper London.

Abstracts of Medical and Surgical Cases treated at the General Hospital for Sick Children, Pendlebury, Manchester. Manchester: J. E. Cornish. 1884.—This is the third year of issue of the abstracts, which are drawn up at considerable labour, and reflect much credit on the staff of the hospital. Special features are made of the cases of scarlet fever, diphtheria, rheumatism, tuberculosis, laryngitis, empyema, heart disease, nephritis, and tumours of the brain. A synopsis of seven cases of typhoid fever in children, treated at the hospital during the year 1883, is given by Mr. F. H. Mayo. An analysis of forty-four cases of croupous pneumonia has been drawn up by Mr. Chester Nance. Thirty-five cases of chorea have been analysed by Mr. Wilson. Dr. Ashby appears to be mainly responsible for the medical account, and Messrs. Hutson and Wright for the surgical cases. We hope for a continuance of these useful notes.

Series of Diet-rolls for Special Diseases. By HARVEY J. PHILPOT, L.R.C.P. London: Sampson Low, Marston, Low, and Searle. 1884.—This series comprises the dietetic treatment of diabetes, gout, and dyspepsia. It is good to have such a concise view of foods as has here been drawn up. The tablets ought to be of service more to patients than to busy practitioners. Every hospital physician must know how wearisome it is to repeat the accustomed restrictions of diet to diabetic, gouty, and other patients. We have often wished that slips were printed wholesale containing the name of every ordinary food in use, with a view to striking out by a few or many dashes of the pen those articles which are forbidden to each individual patient. We do not for a moment lose sight of the fact that no two patients are exactly alike in their alimentary requirements.

A Defence of Harvey. By GEORGE JOHNSON, M.D., F.R.S. London: Smith, Elder, and Co. 1884.—These twenty-three pages constitute a reply to a discourse delivered by Professor Scalzi of Rome in February, 1883. Dr. Johnson's answer appears more than a year later, for the simple reason that he was unaware of Scalzi's publication until it was recently pointed out to him by Sir James Paget. We recommend everyone who wishes to grasp the whole matter of the contention concerning the discovery of the circulation of the blood to peruse the clear statements so aptly laid down by the distinguished author of the Harveian Oration of 1882.

Handy Guide to Public Health. By THOS. W. HIME, B.A., M.B. London: Baillière, Tindall, and Cox. 1884.—An Act of Parliament is generally a cumbersome document, and it is especially so when it numbers several hundred sections; besides which, it needs, for the purposes of the majority, to be supplemented by notes, references, and explanatory comments. All this has been attained by the issue of Mr. Hime's elegant Handy Book of the Public Health Act, 1875; and more too, for its compass is such that it can be carried about with ease. It is supplemented by abstracts from other Acts, Orders, and Memoranda relating to matters with which medical officers of health and inspectors of nuisances have special concern; clauses not bearing upon their duties have been eliminated, and a good index is provided. The Guide is handy, as it professes to be; and it will certainly be useful.



Liverpool Medico-Chirurgical Journal.—The original articles in the current number are:—Surgical Treatment of Hæmaturia, by Reginald Harrison, F.R.C.S.; Cases of Bladder Diseases, by W. Alexander, M.D.; Local Treatment of Respiratory Organs, by Frederick T. Roberts, M.D., F.R.C.P.; Acute Yellow Atrophy of the Liver in Children, by Hyla Greves, M.B.; Syphilis and its Treatment by Erythroxylon Coca, by Fred. W. Lowndes, M.R.C.S.; Gout, by H. Colley March, M.D. All these articles well sustain the reputation of the journal. Mr. Greves' paper is a careful summary of all the principal facts and views concerning acute atrophy of the liver. Dr. Roberts' essay is an able and exhaustive account of the subject of local treatment of respiratory organs.

A Short Account of the Tercentenary Festival of the University of Edinburgh, including Speeches and Addresses delivered on the occasion. Edited by R. SYDNEY MARSDEN. Pp. 217. Edinburgh: Blackwood and Sons. 1884.—As we gave an account of the proceedings at Edinburgh on the occasion of the great festival, it is unnecessary to enter at any length into a notice of this book. We shall content ourselves with recommending it to the graduates and former *alumni* of the University as giving a brief but clear account of the proceedings and an accurate transcript of the speeches and addresses delivered on the occasion, most of them revised by their authors. We regret the want of an index to the book, which would have added greatly to its value.

New Inventions.

PERFORATED INDIARUBBER KNEE-CAP.

THE accompanying diagram is that of a knee-cap which I have recently applied with manifest success in cases of varicosity of the veins about the knee; also those recovering from synovitis of that joint, as well as enlarged bursæ patellæ, and in one case convalescing from transverse fracture of the patella itself. It is made of the ordinary rubber in one piece to any size, and is perforated over every half-inch of its surface. The advantages claimed by this over the usual appliances of silk and cotton elastic web in ordinary use seem to me to be: 1. That it gives a better and firmer support to the affected part, thus affecting a more speedy recovery. 2. It is more durable, and therefore less costly. 3. Being perforated, and, from its structure, more elastic, it keeps the part cooler, and exerts less undue pressure upon it. They are manufactured by Messrs. Mappin and Co., instrument-makers, New-street, of this town, who can supply any size.

Birmingham. HUGH THOMAS, M.R.C.S.

INTERNATIONAL CONGRESS OF SURGICAL AND ORTHOPÆDIC INSTRUMENT MAKERS.—The second annual meeting of the International Association of Surgical and Orthopædic Instrument Makers will take place at Dresden on September 14th next. The object of this Association, which was founded only last year, is to attain by mutual instruction the highest standard of excellence in the improvements of instruments and mechanical appliances, assurance of priority of inventions, and to exclude intermediate dealers, who from want of technical knowledge furnish instruments of inferior description. The Secretary, Mr. C. Walter-Blondetti, Basle, or Mr. C. W. Krohne, 6, Duke-street, Manchester-square, London, W., both members of the committee, will receive the names of persons desirous of assisting in the forthcoming Congress.

THE LANCET.

LONDON: SATURDAY, AUGUST 30, 1884.

ONE of the most important problems in respect to pathogenic micro-organisms is whether, under any conditions, these can be developed from organisms having no such specific quality. The statement has been made that such is occasionally the case, and the instance of the bacillus anthracis is quoted as affording proof of this. The importance of the matter is enhanced by the fact of attenuation of the virus, which has led to the adoption of measures of preventive inoculation. Again, the question was raised by Dr. KOCH in reference to the cholera bacillus, as to whether, under any conditions, this could have been transformed from a harmless variety. The latest contribution to the subject is that of Dr. KLEIN, published a few weeks since in an Interim Report to the Medical Officer of the Local Government Board, and the results of his researches may be summed up in the statement that there is no sufficient ground for the belief that septic can be transformed into pathogenic organisms. At present he says it is a debated question whether an organism which under ordinary conditions is only to be met with in association with putrefaction, can under extraordinary conditions become endowed with the power of growing and multiplying in the body of a living animal so as to induce therein an infective disease. If the converse can be proved—viz., that a micro-organism known to be pathogenic can be made to lose its property, ground might be given for that conclusion. The instance of the bacillus anthracis and its attenuation is shown by Dr. KLEIN to be of less significance than is supposed, for he finds that when new cultures are made the bacilli retain their full virulence. At the same time the fact that these bacilli do apparently lose their pathogenic activity is undoubted, and it is explained by Dr. KLEIN by the assumption that such a change is not an intrinsic one, but in all probability due to the bacilli appropriating, under certain conditions, some chemical substance or ferment which produces a weakening effect upon them; and that the immunity conferred upon some animals depends upon the restraining influence of this substance on the activity of the bacilli. He quotes in support of this the attenuation produced by the addition of carbolic acid or bichromate of potash to the nutrient medium in which bacilli are cultivated. The inhibiting material, probably of various kinds and nature, does not operate in preventing spore-formation or in checking the growth of the bacillus. Nor does it modify the virulence of subsequent inoculations with other fresh bacilli, so that on this view protective inoculation with "attenuated virus" is reduced to a vanishing point.

Dealing next with the three alleged examples of the conversion of a putrefactive or septic organism into a specific or pathogenic one—viz., BUCHNER's view of the transformation of the hay bacillus into bacillus anthracis, the assumption of pathogenic properties by the bacillus subtilis in jequirity infusion, and of aspergillus when grown in neutral and alkaline material—Dr. KLEIN in the first place points out that the hay bacillus differs morphologically from the anthrax bacillus, and also in its mode of growth and action in culture fluids. He deals with BUCHNER's arguments in turn, and proves that KOCH was right in rejecting them, and that the alarming doctrine that the hay bacillus is capable of being transformed into the pathogenic anthrax bacillus is chimerical. Each of these organisms is distinct from the other during its whole existence, and the only explanation of the error that has been made in arriving at a different conclusion is that of accidental contamination. Dr. KLEIN gives instances of the remarkable way in which such contamination can take place without the experimenter's knowledge, and amongst them he quotes the erroneous conclusion respecting the artificial production of tubercle in rodents by non-tubercular substances, which were quite upset when sufficient precautions were taken to avoid such contamination. Nothing illustrates better the extreme care that is required of the experimenter in his researches on these microscopic and ubiquitous organisms; and how a quite unintentional oversight may vitiate the whole result and lead to the formation of a quite erroneous conclusion. Then as to the jequirity bacillus, concerning which so much has lately been written, owing to the practical use to which this substance has been applied in exciting ophthalmia, Dr. KLEIN shows that *per se* this organism (the bacillus subtilis) is as powerless to create an infective ophthalmia as BUCHNER'S hay bacillus is to cause anthrax. For by taking suitable precautions he has obtained a perfectly sterile infusion of the jequirity seed, and has shown that this possesses the property in question. Further, he finds that after a very short exposure to the air this infusion contains a large quantity of bacilli derived from spores floating in the air, and that boiling which deprives jequirity of its poisonous action does not destroy the spores. To Dr. SATTLER's statement that cultures of the bacillus can excite ophthalmia, Dr. KLEIN urges that this must have been due to contamination with some of the original jequirity infusion, for by isolating the bacillus and cultivating it through two generations he was unable to produce any poisonous effects. Lastly, as to the aspergillus, which GRAWITZ showed to have infective properties when injected into the blood, he concurs with KOCH and GAFFKY in the belief that certain species of this fungus possess pathogenic properties *ab initio*, whereas others are non-pathogenic, and can never acquire such properties. Similar explanations hold for the forms of septicæmia and pyæmia produced in mice and other animals by injection of putrid organic substances—namely, that such infection is due to organisms that are pathogenic throughout, but capable, like the anthrax bacillus and the micrococcus of erysipelas, of growing outside the animal body. A final section of the report details the negative results (*quoad* pathogenic action) obtained by inoculations with various forms of non-pathogenic micrococci and bacteria. In these experiments the singular result was found that inoculations of bacillus subtilis in mice were followed by a fatal pyæmia; which, however, on examination was proved to be due to the presence of a micrococcus, that obviously could not have been derived from the bacillus, but must have been introduced accidentally when the

Digitized by Google

latter was inoculated. As a contribution to a very vexed question, and as supporting very strongly the notion of specificity under prevailing conditions, these researches of Dr. KLEIN deserve careful attention.

DR. MOXON'S picturesque sketch of the character of the late HILTON FAGGE is as full of truth as it is of humour. It would be easy to compile a chapter of aphorisms from the columns we print elsewhere, and each might be made the text of a homily for the edification of medical men. We scarcely know which most to admire, the subject of the sketch or the work of the sketcher. This much we must be allowed to say before we proceed to jot down briefly a few of the thoughts which the perusal of Dr. MOXON'S paper has suggested.

"Five-sense philosophy" is beyond question the true definition of science as it falls within the ken of the medical student and practitioner. To see clearly, hear distinctly, and bring all the organs of the life-of-relation to bear on the subject matter of study and work, is the duty, the privilege, and the safeguard of the physician. To be able to do this worthily is to be what Dr. MOXON aptly calls "a physician by grace of nature." Meanwhile something more than this is necessary if the physician is to be great in a true sense. There must be "the identification of self with interests that are socially constructive and positive and real." This is a sentence that should live. It is pregnant with the soundest of good sense. It goes right inside things, and takes a human view of facts and the world and nature. It does not prate of "unselfishness" or "self-sacrifice," those utterly absurd and canting hypocrisies of a maudlin moral sentiment, but sees clearly, and candidly admits that a man must be selfish—if he be a human creature; and only asks as the proof and fruit of his greatness of mind that he shall identify his selfishness, his self-seeking—let us be plain—with social constructive and positive and real interests. How much more forcibly does this appeal strike home to the consciousness, and how much greater the influence it exerts on the will and the life, than mere vague platitudes about the grace and beauty of unselfishness! It seems to say to the heart honestly and intelligibly, This is the way; walk ye in it.

As Dr. MOXON justly affirms, "It is so tawdry easy to be free and negative." If nothing more than an odour of sanctity and a halo of sentiment were needed to make a man good and great, educated folk who have been decently indoctrinated would be paragons of virtue all the world through and in every profession! To be *positive* is altogether a different and higher attainment, and few there be that achieve it. The truly great physician must be gifted with not one but all the five senses, and he must have them, or their inner counterparts, in the intellectual being, properly concerted for action under the directive and protective guidance of a well-balanced mind. Then he must be thoroughly honest, and as patient and persevering as he is energetic. It is one thing to be able to see truth, and another thing to understand it; and yet another to love and reverence it for its own sake. The true scientist has nothing to do with the "limbo of faithless questioning and faithless doubting" which lies beyond the reach of a "five-sense philosophy." It is strictly true of that limbo, as Dr. MOXON puts it, that therein "the luxury of doubting makes science as impossible as it makes religion." The true man, who is also a scientist, never wanders over the borders of that limbo, because he simply goes as far as his five senses will carry him, and not a step further. He does not deny that there may be things beyond his reach. He is quite prepared to believe that "if GOD had given us two or three more senses we should have experienced just so much more" of the analysis and the revelation of nature, as those additional faculties were able to appreciate. He is not free and negative, and therefore he does not feel at liberty to affirm a negative. He humbly accepts the known, and without superstition pays reasonable homage to the unknown.

Those who do not think—and there are too many of us to whom real thinking is a rare exercise of the understanding—have no adequate notion of the nature and qualities of true greatness in medical life and work. It is one thing to have a grand "action"—as a horse may have,—but quite a different thing to be really grand. The two qualities are not only separable, but often separated; we might almost go the length of saying that they are seldom found together. Just as the advanced scientist is seldom a practitioner, so the man who has been endowed with those powers which fit him for the discovery and collocation of facts is not, as a rule, also found gifted with the faculty of using his gifts as "traps to fortune." And as a "belief formed on sense-knowledge" saves from metaphysics, "which is mental humanity floundering with eyes all round the back of its head," so the earnestness that inspires by a consciously "sure grasp of the reality and the practical significancy of truth" renders the mind incapable of stooping to the commercial enterprise of packing and retailing small parcels of truth as a marketable commodity. It is not so much that the wholesale dealer is superior to the petty shopkeeper, as that he is so engrossed with broad views and large considerations that he cannot bring his mind to the narrower and smaller subjects of thought and purpose. Both the merchant and the shopkeeper are good and necessary in their respective places. The retailer and adapter of knowledge is as much in request, and rightly so, as the collector and comparer of facts and the drawer of inferences; but the two are distinct. If there be a defect and danger in the genuine hero-worship which prevails, and must always prevail, among the disciples of true greatness in science, it lies in the failure to recognise that giants would cease to be great if the average stature of man were equal to the ideal of our idolatry. It is neither necessary nor reasonable to condemn the mice on the score that they are not lions, because sometimes the lion may be indebted to the mouse. The great physician may be indebted to the little practitioner. It is not given to every good and earnest man to be a head and shoulders taller than the rest of the people; but it is none the less to the advantage of all to look up to the truly great—men like HILTON and FAGGE, whom Dr. MOXON so truly and eloquently characterises as "men in whose presence the faculty of imitation was a blessing, and made a better man of you."

THE Health Exhibition has much to answer for. Amongst the rest it is responsible for a very warm discussion on the merits of Alcohol. A leading contemporary had it in its

Digitized by Google

power to allow that delicate question to sleep. But it is a tempting one in the dull season; and the temptation proved too great to be resisted. Accordingly, coincidentally with the summary of the session, *The Times* published a very able digest of the alcohol question, decidedly from another standpoint than that of the humanitarian or the teetotaller. The writer argued that the dominant nations have all used alcohol in some form or other. Those who wear the badge of abstinence are obviously persons of inferior physical development, and, so far as they can be judged by facial expression, not "remarkable for intellectual power." The best work of the world is done by moderate drinkers, and, as far as we are aware, the work of total abstainers is of a very commonplace kind. Barring cases of manifest disease, drunkards now are either professional criminals, who had better be drunk than sober, or persons of slender self-control, who are ready at any time to lapse into criminality. There may be half a million such, and they are so worthless as to make it wrong for the remaining twenty-nine millions and a half to exchange moderation for abstinence on their account, or with the vain hope of doing them any good. Such people drink on account of a morbid state of the nervous system, inherited or acquired. When reclaimed by teetotalism, they are striking examples of its power, but the ordinary experience is that after many relapses they ultimately die, directly or indirectly, from the effects of drink. On the whole, the writer concludes that the teetotal societies do very little good and a great deal of harm. It was not to be expected that such a summary of the alcohol question as this could be accepted by the teetotal section of the community without much pain and protest.

It is to be regretted that on each side of this controversy there seems an indisposition, almost a determination, perhaps an incapacity, to see the best points in the argument on the other side. It appears almost as if there were something in the nature of alcohol that affects all who think about it, even those who abstain from it, with a kind of intemperance. The intemperance of teetotallers has greatly hindered the cause of temperance. Their denunciations of moderation and of moderate drinkers have estranged whole classes of men that would have brought strength and help to the cause. Their dogmatism about what constitutes food and what poison, and about the injurious effects of every drop of alcohol, has excited ridicule and laughter rather than intelligent interest. Their refusal to see that many who are not against them are on their side, and their general attitude of superiority, have been most unfortunate. By such an attitude the medical profession has been prevented from hearty co-operation with those who see in the drunkenness of the country a gigantic evil and disgrace, to be remedied at any cost short of that of talking nonsense. Similarly, a large section of ministers of religion have been obliged to stand aloof from those who, against Scripture, common sense, and examples of the good in all ages, have refused to recognise in wine and its congeners things capable of use as well as abuse, and things to be reasoned about calmly in the light of experience and science.

One result of this extreme position on the part of teetotal reformers is to bring down on them and their cause such cold water as the article which occasions our present notice of alcohol and its *rôle* in human life. We cannot much approve of the article in our contemporary, but it is rather of its tone and spirit than of its substance that we have to complain; rather with its scant and reluctant praise—its actual dispraise—of men with a great cause and with good motives, than with its scientific propositions, that we have to quarrel. The world is not so much in danger of neglecting to take a proper amount of alcohol that it needs three or four columns of ingenious argument to prevent it falling a prey to indigestion and nervous exhaustion from drinking water alone. But the excuse for such writing would be less if there were a little more reasonableness and temperance on the part of those who seek to abate the national consumption of alcohol. Their case is by no means so contemptible, logically and medically, as the writer referred to above would make out. There are some very good-looking fellows among them; they are not by any means intellectually contemptible; they live quite as long as, if not longer, than other people, and escape many diseases that affect others, though they have their own liabilities; they are good workers. There may not have been yet a teetotal SHAKESPEARE or MILTON—there has not been time;—but much of the best work of the world now-a-days is done by men who either do not use alcohol or use it in such quantities as to be inoperative physiologically or pathologically. And the common work of the world is done well by abstainers; they are industrious, reliable, healthy. According to Lord WOLSELEY they make good soldiers. Sir WILLIAM GULL has said that "it is one of the commonest things in our society for people to be injured by drink without being drunkards. It goes on so quietly that it is very difficult to observe. To the professional eye the effect is perfectly marked and distinct." Many other eminent men have given similar testimony. So that there is an amount of drinking deemed moderate by society which, in the opinion of judges, is very injurious to the liver, the lungs, the nervous centres, &c. Further, the actual impression made by the teetotal school on public opinion and social habits is considerable, so that sensible men do not take stimulants in the quantities they used to do, or on an empty stomach and without food. No doubt much of this is due to sounder medical science and to the extreme moderation of medical prescription and example. But part of it is due to teetotalism and to religious efforts to promote sobriety, which it should be the desire of everyone to second, the more so as there is still a frightful amount of ignorance abroad as to the impunity with which alcohol, even in strong forms, may be taken into an empty stomach. A physiologist may still be shocked every day in a restaurant or a railway refreshment room—of course physiologists never go into public-houses—by seeing young men order and toss off without thought and without food glasses of spirit more or less raw. He knows how infallibly and how quickly that leads to mischief. But for evils and follies like this there is room for common protest and effort, apart from intemperate doctrines of teetotalism on the one hand, and too easy disparagement of those who hold them on the other.

UNDER the title of "A Romance of War, or how the Cash goes in Campaigning," Dr. CAMERON, the Member for

Digitized by Google

Glasgow, has published a brief summary of the facts brought out in evidence before the Select Committee of the House of Commons, which, on his motion, was appointed to inquire into the working of the Supply and Transport Services in the Egyptian campaign. He has adopted this somewhat unusual course in anticipation of the publication of the Report of the Committee, in consequence of an article in *The Times*, which, it was clear to him, "was directly inspired by the War Office," and in which the correspondent asserted "that with regard to failures in the working of the supply and transport services at the seat of war the evidence seemed to show that there was none," and that "it seemed manifest that the expedition as a whole was, from a purely administrative point of view, a success." A perusal of Dr. CAMERON'S pamphlet has led us to a very different conclusion, for it would be difficult to imagine a more complete picture of rascality, incompetence, ignorance, and mismanagement than is there represented. It would be beyond our province to go into the whole question, but we may note what he has said regarding the Medical Transport. The mules, which had been trained for *cacolets* or litters for ambulance service, were taken to make up regimental transport, and replaced by untrained animals from Spain. These on arrival at Ismailia were at once appropriated to the important work of dragging trucks on the railway; and when the principal medical officer applied for others, in anticipation of the battle of El Magfur, he got only fifteen, and these so utterly unsuited for the work that he would not allow any wounded men to be placed on them. Dr. CAMERON sums up the history of this branch of the service in these words: "Inability to move forward field hospitals for want of transport, and army hospital corps taken away from their proper duties to remedy, as far as they could, the want of transport and labour." Dr. CAMERON exonerates the Commissariat and Transport Department from much of the blame attached to the shameful mismanagement and blundering which took place. The head of the department was not consulted as to the purchase of stores or transport animals, nor in the selection of carts or shipment of stores; his request for labour was disregarded; and when, on appointment, "he busied himself with suggestions and demands, he was given to understand that his interference was not desired." The officers of the Department very fairly complain "that under the existing system, in time of war they are debarred from performing the duties to which they are trained in time of peace, and are blamed for the miscarriage of supply and transport arrangements, in carrying out which they have had no voice." In an appendix Dr. CAMERON has pointed out the waste and extravagance which occurred in connexion with the transport service in the Afghan War. The facts which he has brought before the public in connexion with these two expeditions will, we trust, compel the War Office authorities to consider carefully the whole question of commissariat and transport arrangements, and lead to the introduction of a system which may be relied upon in the hour of danger, so that our troops may not be placed in circumstances similar to those in the Crimea and Egypt whenever any unusual or unforeseen event may occur in the course of field service. Dr. CAMERON is entitled to great credit for the persistence with which he has followed out this inquiry, and we most sincerely trust that his labours may be followed by those improvements in organisation and working which he has been so anxious to see introduced into our army.

THE principal points secured by the Amended Canal Boats Act are the registration of such boats and the maintenance of the education of children connected with them. Provision is made for frequent inspection by local registration and sanitary authorities, and by the Education Department, with the presentation of annual reports to Parliament directly or through the Local Government Board. The enactment of these regulations, by giving efficiency to a measure at one time too loosely administered, has supplied a want which cannot be said to have been unfelt because perhaps not fully realised by the nation. The registration and supervision of inland water traffic are at certain times and in several ways not less important to the public interest than those of the mercantile marine. On July 5th we drew attention to the obvious bearing of such a system on elementary education and on the detection of crime. With reference to school instruction particularly, it must be clear to all that without some special action on the part of the Government, many, if not most, of the boat children must grow up in ignorance. The difficulty of obtaining regularity of attendance is not considerable, even in the most settled circumstances, but it is greatly increased when to many accidental causes of absence is added the fact that the home itself is a ready means of transit over wide areas. Under no conditions, however, is it likely that the beneficial operation of the Act will be more apparent than in the presence of infectious diseases. Foci of population are, of course, foci of diseases, and not only of such as are endemic, and in so far autogenetic, but in the case of commercial towns of exotic and epidemic maladies which come to them as the accidents of trade. The good effect of inspecting the state of health of merchant vessels has been well shown in the prevention of the spread of cholera which recently approached one or two ports on our own shores. The control of the next link in the invasion of an epidemic, the commercial centre, is carried out by the sanitary department. It is no less necessary that the further communications with the interior of any country should be controlled with equal strictness, and of these the inland waterway is perhaps the most important. The canal population while under cover is peculiarly subject to the hurtful influence of overcrowding, bad ventilation, and restricted means of cleanliness. Clearly, then, if disease be planted and reared in circumstances so favourable to its growth, the results may be understood without description. Everything relating to these boats, therefore, their starting point and destination, their crew, cargo, and accommodation, and not less their disposal of refuse and their use or abuse of the waterway for this purpose, are matters of much and general consequence, and justify the official regulation which they have received.

SURGEON-MAJOR FERNANDES, of the 3rd Battalion Grenadier Guards, was on the 21st inst. at Dublin acquitted on the charge of felony, the jury expressing the opinion that the accused left the Court without the slightest stain on his character.

Annotations.

"Ne quid nimis."

"LEGACIES TO THE HOSPITAL SUNDAY FUND."

DR. WAKLEY'S suggestion that benevolent persons who have money to bestow should leave it to the "Hospital Sunday Fund" instead of to particular hospitals is eminently practical, and we are convinced that, on consideration, it will be found to be sound. It is impossible that any individual, however judicious, should be able to arrive at so good an estimate of the work of a hospital as a committee having for its permanent function the consideration of the claims of the hospitals generally to pecuniary assistance. It must be obvious that the Council of the Hospital Sunday Fund is peculiarly well placed for the formation of correct judgments on the cardinal points of a hospital claim—namely, its value to the sick poor, its service in the cause of science and consequently of the public, and the wisdom and fidelity of its administration. It will be of great and lasting advantage to the interests of humanity if Dr. Wakley's suggestion is accepted and acted upon. We can readily understand that, on the first blush of the case, it may seem more congenial to the feelings of a testator to make his own choice of a charity to which to leave his bequest; but on reflection it will be perceived that the wisest course must be to entrust the duty of distributing aid to a responsible committee able and willing to make the best possible use of any fund for the general advantage. The recommendation is as simple and obvious as it is just, and neither argument nor explanation is needed to enforce it.

THE ORIGIN OF SEA-BATHING.

THE sea was held in dread by classical antiquity; immersion in its waters was an experience to look back upon with a shudder; and the Greek or Roman who came out of it alive repaired to the nearest temple, and there suspended his dripping garments and a votive tablet to the forbearing Poseidon, or Neptune. This horror of the sea descended to mediæval times, when indeed ablutions of every kind were almost dispensed with, and the human integument so sparingly refreshed with fair water as to earn for the Ages in question a double title to Dark. A compulsory dip in the sea was a sentence sometimes passed on the mediæval offender, often with exemplary effect. The legend has it that a first-class misdemeanant, who, though ill at the time, was visited with this penalty, emerged from it so much the better physically as to shake belief in its deterrent virtue. Ronsard, the French poet and scholar, sang the praises of the ocean and its health-giving waters, but this was only a faint and far-off anticipation of its modern worship. It was in England and towards the middle of last century that the sea was first recognised as the mighty sanitary agent the world now acknowledges it to be. At that time Western Europe was heavily scourged by scrofula—king's evil, as it was called—and all ranks of society, from peer to peasant, were more or less sufferers. Dwellers on the seaboard, guided by instinct apparently, drank of the briny water, bathed in it, washed their sores in it or bound them up with seaweed. And they had their reward in physical as well as moral invigoration. The profession took note of this practice, and Dr. Russel, a Court physician, who was the first to become cognisant of it did not wait for a chemical or physiological theory of its efficacy, but prescribed it at once to his patients, and was followed by others of his contemporaries. Soon the English coasts were planted with villas and cottages; and hamlets, from their sea-bathing advantages, expanded into towns. At the close of last century Germany imitated England, then Belgium, then France, until in the year 1812 Dr. Lefrançois of Dieppe published a treatise on the internal and external virtues of sea-water, and raised his native town into a much-frequented health resort. So that from having been first used in scrofula, the touch of ocean is now employed in countless other evils than the "king's"; and invalid Britannia repairs, with yearly recurring alacrity, to the waves over which she rules.

EXPERIMENTAL NEURITIS.

CLINICAL observations of motor and sensory paralysis, in certain cases, after the hypodermic injection of ether, have led MM. Arnozan and Salvat to study the action of ether and cold on the peripheral nerves. The first experiment was made on the left sciatic nerve of a guinea-pig by exposing the nerve and isolating a few centimetres of it on a thin strip of cardboard. Under these circumstances the application of a feeble electric current induced pain. By the aid of a drop measure ether was instilled over the nerve for thirty minutes. The nerve was then replaced and the wound sutured. The next day and the day after there were manifest signs of paralysis and loss of sensation in the left hind limb. At the necropsy the wound was found to be free from suppuration, and with the exception of redness of the nerve at the site operated on there was no disease in the limb. Sections of the inflamed nerve showed segmentation of the myeline. In the second experiment the right sciatic nerve was simply exposed to the air for half an hour. The sensibility of the corresponding limb was a little lowered and the movements were a little weakened; these disorders passed away in a few days. Some days previously, however, the left sciatic nerve of the same guinea-pig had been isolated, but instead of simple exposure to the air it was surrounded with ice for half an hour. At the end of that time, though the edges of the wound were not anæsthetised, yet the sensibility was notably diminished in the limb below the part operated on, and the muscles supplied by the nerve were paralysed. At the end of four days the sensibility had returned to the normal and the muscular paralysis had passed away; moreover, after some weeks the faradaic reactions of the muscles were quite natural. Nevertheless, trophic lesions were observed. The limb was at first much wasted, but this did not last. The hair had all fallen off around the wound fifteen days after the operation. At the same time ecchymoses were seen on the left heel, which afterwards became ulcerated. All the nails of the foot were shed. Later, the ulcer healed, the hæmorrhage disappeared, and the limb became sound. No signs of neuritis were discovered microscopically after the animal was killed. The authors point out the interesting observation that the trophic troubles lasted much longer than either the sensory or motor paralysis.

TWIG AND TREE.

"JUST as the twig is bent the tree's inclined." Pope's monumental verse inspires philanthropic effort in every stratum of society, from the crusade against overpressure in schools to the various attempts at organising a moral *orthopædia* for the development of the boy into the man. The impressionable and plastic nature of childhood is not secured against distorting influences by surveillance over its school-life only. At home much remains to be done and much is disastrously done in the moulding of early character, and in determining the career of ingenuous youth. The Society for the Prevention of Cruelty to Children just formed at Glasgow hits a blot in our educational system, and deserves imitation wherever the juvenile population, of the lower strata especially, is numerous enough to overtax the control of schoolmaster, clergyman, and parent alike. The diffi-

Digitized by Google

culties thus engendered in humbler families occasion nine-tenths of the cases of maltreatment which come from time to time before the magistrate; just as in lunatic asylums where the surveillance is insufficient the much-exercised keeper is goaded into acts of cruelty to intractable inmates. The maltreatment of children, however, has its passive as well as its active side, and it is questionable whether absolute neglect of them is not more prejudicial to their development and future well-being than the savage usage they encounter from evil-tempered parents. The Earl of Glasgow, who presided at the first meeting of the Society above mentioned, dwelt ably on the problem it it had set itself, of which he indicated a threefold solution. Legal coercion may prevent the maltreatment of children; in difficult cases knowledge gained by careful study and experience of the scope of existing laws may be effectively applied; while moral suasion, exerted, for example, on too indulgent or practically negligent parents, might come in abatement of their co-operating with the children's dislike to school or of their failure to check premature smoking and drinking, those frequent causes of diseased development, physical and moral. The Society, Lord Glasgow was careful to show, sought in no sense to supersede parental responsibility; but, on the contrary, to enlighten and to stimulate it. It further dissociated itself from all attempts to interfere with the religion of the children within the scope of its operations; nay, protection of their faith, as well as protection of their persons, was part of the Society's programme. That programme is, indeed, in the best acceptation, a humane and enlightened one, and we are confident our professional brethren, wherever a similarly instituted Society may spring up, will give it the sympathy and the co-operation they have never withheld from any nobly intentioned and well-organised undertaking.

TUBERCULAR SEROUS EFFUSIONS.

AN experimental study by MM. Chauffard and Gombault of the virulence of certain pleural and peritoneal effusions is still in progress, though a preliminary report has been published in the "Bulletins et Mémoires de la Société Médicale des Hôpitaux." These observers, having never been able to discover the bacillus tuberculosis in peritoneal or pleuritic effusions, which were obviously of a tubercular nature, determined to employ the experimental method. Instead of making use of the artificial cultures, as recommended by Koch for the demonstration of the bacillus, they resorted to the living organism, and for the most part the guinea-pig. The *raison d'être* of these researches is easily told. If the bacilli be present in the morbid fluids, but are so sparsely scattered that their histological demonstration is almost impossible, the method of cultivation so as to increase and multiply their number is obviously the plainest way out of the difficulty, seeing that the bacillus cannot multiply if it be not present. Injections of the serous fluids have been performed in the subcutaneous tissues of the guinea-pig by means of a Pravaz syringe or Potain's apparatus. Super-heating the trocar and needle and repeated washing of the instruments with antiseptics were the precautions used. About three cubic centimetres of the serous fluid were injected into the peritoneal cavities of a number of guinea-pigs. The animals were killed at intervals of two, three, or four months. Twenty-three guinea-pigs and twenty-one serous effusions were employed in the first series of experiments, one patient serving to inoculate three animals. The fluids inoculated were either serous, sero-fibrinous, or purulent. Of the twenty-three inoculations, four gave no result, the animals having died rapidly. In nine, the autopsy made at the end of three or four months revealed no tubercular lesions. In one case a positive result, the necropsy discovering miliary and yellow tubercles, as well as infiltrations, in the liver, spleen, and lung. The spleen was always considerably enlarged, and a number of mesenteric and peritracheal glands were swollen and partly caseous. The great omentum was also infiltrated. Sometimes there were lesions of the intestines, and also of the genital organs. The kidneys were usually spared. Characteristic bacilli were discovered in all the cases where macroscopic tubercular disease was present. The existence of widespread lesions of tubercular appearance and the detection of the bacillus were taken as sufficient criteria of tuberculosis, so that a further series of inoculations was not undertaken. Of course Gombault and Chauffard believe the tuberculosis to have been due to the inoculation. All the inoculated animals lived together in three or four hutches, and with them a certain number of non-inoculated ones to serve as test experiments; none of the latter became tuberculous. That the mere puncture could hardly have been the cause of the tuberculosis was shown by the escape of nine animals. M. Déjérine, joining in the discussion which followed the reading of the paper, said that he had succeeded in demonstrating the bacilli in purulent effusions by allowing the fluid withdrawn to stand, and then, decanting the liquid, to search in the lower strata for the bacilli. M. Gombault admitted the facility with which bacilli in purulent fluids were demonstrable, but said that decantation failed when serous or sero-fibrinous effusion had to be dealt with.

THE SANITARY STATE OF WIGAN.

THE sanitary state of Wigan is, according to the statistics published by the Registrar-General and to details given in the local papers, deserving of very serious attention. Scarlet fever has now for many months past been widely prevalent throughout the district, and, in a population of some 50,000, the deaths from this cause alone have numbered 67, 61, and 58 respectively during the past three quarters. What the efforts which are being made to check the progress of the disease may be we cannot say, except in so far as they include some measures of school closing and disinfection; but it is very certain that the principal measure by which the outbreak should have been met at the onset—namely, effective isolation—could not possibly have been brought to bear upon the extending disease; for Wigan, with its large population, has only for an infectious diseases hospital an old villa, with three available bedrooms. The startling mortality from scarlet fever has led to revelations concerning "Insanitary Wigan," and to conditions of housing in connexion with prevalences of enteric fever, which, if not exaggerated, reflect the reverse of credit on the sanitary authority. In a street leading out of Frog-lane, for example, a correspondent of the *Wigan Examiner* finds twenty-seven cases of this disease. In a district called Scholes, with its "damp alleys, its damp and decayed houses and ear-rotted inhabitants, who herd and are packed together like negroes in the middle passage," the sanitary conditions as described are of a revolting character. Stopped-up drains and sewers, stagnant and offensive filth, garbage in an advanced state of putrefaction, liquid manure, open middens and closets, &c., were met with, all indicating that, whatever nuisance inspection may be carried on, little is done towards preventing the recurrence of nuisance by adequate permanent works and structural alterations. The overcrowding which exists in this locality must be as subversive of all decency and morality as it is opposed to physical health. In one place, a man and his wife, with their family of young men and maidens, whose ages varied from eighteen to twenty-seven years, all slept in one filthy, grimy room. Elsewhere a man aged thirty-six and a girl aged eighteen slept in the same dormitory with their parents. Again, two young men and their wives and a young unmarried woman of twenty-two years of age occupied one small sleeping apartment. This

Digitized by Google

certainly is a state of things which should be put an end to. Section 90 of the Public Health Act, and the corresponding section of the Sanitary Act of 1866, were specially framed to meet such conditions; and it behoves the corporation to secure without delay such supervision of houses so sublet as shall lead to the abolition of such intermingling of sexes as has been described. The necessary bye-laws and regulations are also urgently needed in the sanitary interests of the houses and of their occupants.

DR. SHOEMAKER'S OLEATES.

IT would be difficult to over-estimate the value of the different oleates and oleo-palmitates in the treatment of various forms of skin disease. The subject is by no means new, but attention has been directed to it of late by papers and experiments recently published by Dr. Shoemaker of Philadelphia. In THE LANCET of July 19th we gave a full report of a lecture on this subject delivered by him at the Westminster Hospital. His oleates are prepared from the sodium oleate by a process of double decomposition, and it is claimed for them that they are definite chemical combinations, differing entirely from the old so-called oleates, which are nothing more than solutions in an excess of oleic acid. These new oleates are undoubtedly very useful compounds, and it is probable that many of them, at all events, will come into extensive use. The zinc oleate is a fine pearl-coloured powder resembling French chalk, and when mixed with a small proportion of thymol forms an excellent dusting powder for all kinds of excessive sweating. The oleate of copper is used in the treatment of ringworm and other parasitic skin diseases; and it is said to be a good application for freckles. The mercurous oleate is found to give good results in plantar and palmar psoriasis, and in old cases of eczema, especially when the integument is hard, dry, and thickened. The oleate of bismuth is a bland, soothing application adapted for the treatment of acute eczema and other inflammatory conditions. There are some twenty or thirty oleates in all, each having its special use and sphere of action. The oleates of various alkaloids have been prepared, but they are of comparatively little importance, and their therapeutical indications are as yet not well established.

THE VACCINATION PANIC IN LEICESTER.

IT is to be hoped, in the interest of Leicester and of the whole country, that the waywardness of that town in regard to vaccination has reached its height. Twelve hundred persons are awaiting trial, and others are now undergoing terms of imprisonment, for having evaded the Act. In such a case there is but one course open to the authorities—namely, to execute the law with just though moderate firmness. It cannot be permitted that one town, even though not large and protected from contagion in some degree by its comparatively secluded position, should become the possible centre of an epidemic. At the same time all must regret that compulsion should be required to support a measure of the undoubted practical value of vaccination, and those who know the characters of small-pox and its history in this country must be driven to the conclusion that this, its only remedy, has been resisted by some simply because its successful operation has shorn the disease of much of its terror. There can be no question that the opposition in Leicester rests chiefly upon misunderstanding. It has been maintained by agitation, conscientious enough, perhaps, but inspired by misinterpretation and irrational feeling, which would seek to fix on vaccination the discredit due to neglect or constitutional fault, and in no way connected with it. In these days every facility is afforded to the qualms of diffidence. One may be vaccinated where, by whom, or from whom he chooses; he may go to the infant or the calf, and may adopt almost any measure he pleases to satisfy himself of his security. In the face of all this consideration—we might say unnecessary consideration—for nervous apprehensiveness and of the essential safety of vaccination itself, the rebellion in Leicester must appear to most people as meaningless as it certainly is injurious. We recommend all who now oppose this practice to consider the subject from every point of view and with every kind of proof, and we do not doubt that they will then admit that a custom which has fairly won and holds its ground in every civilised country does not deserve, as it never can experience, the swift perdition to which they would consign it.

DISUSED BURIAL GROUNDS.

THE Disused Burial Grounds Act, which has for its chief object the prohibition of building within the spaces described in it, is a fairly complete measure, though not in our opinion quite perfect. Certain buildings which are required for purposes of worship are exempted from the prohibition referred to. The advisability of any such exemption is open to question, inasmuch as the opening of graveyards, even after long disuse, has in several cases been followed by outbreaks of local disease, referable to no other cause than exhalations from the disturbed sites of burial. Any risk from this source is necessarily increased if excavations should happen to be made during the prevalence of infectious disease in a district. In any case where such excavations are carried on, it should be a part of the duty of the sanitary authority to superintend them and to take whatever measures may be necessary to obviate all danger to health from the burial ground itself, or from the use of the building erected on it. We cannot leave this subject without once more recommending that as many such vacant spaces as possible may be left free of buildings, and converted into playgrounds, with appropriate means of amusement for the many town children who might profit by such an arrangement. The disturbance of soil from such a proceeding would be trifling, and the substitution of tottering gravestones and nameless garbage by flowers and level pavements would be a point gained in health as well as in beauty.

CHOLERA MICRO-ORGANISMS.

THE more one considers the subject matter of Dr. Koch's researches the more one is convinced that amongst the numerous workers who have been engaged in the search after specific organisms in cholera there must be several who have seen the same objects he describes, without, however, having attached to them the same significance. In lately referring to this matter we gave a hasty glance at some of these previous efforts, based upon the review afforded by Hirsch in his well-known work. One name was omitted wholly unintentionally, and perhaps rather strangely, seeing that a few weeks before we had published a letter from Dr. A. H. Hassall upon the special point. In justice to him we are pleased to revert to his researches made more than thirty years ago, and to be found in his report to the Government of 1853. We should be sorry, indeed to think that the labours of one who amongst us has been a pioneer in microscopical analysis had been overlooked, and therefore we mention Dr. Hassall's name here in order that full justice may be rendered him. We are reminded that amongst the forms he detected and described were some spiral-shaped threads much resembling those which Dr. Koch believes to be a further stage in development of the comma bacilli. It is, we confess, highly probable that what Dr. Koch saw in 1883 Dr. Hassall perceived in 1853. It is one penalty we have to pay for the high-pressure life of the present day that new discoveries are made because the old ones are forgotten, and the labours involved in the latter are lost sight of in the present glories

Digitized by Google

of the former. Of course the lines of investigation pursued by Koch are, as compared with his predecessors, quite novel and searching; for he does not content himself with mere detection and description, but studies his micro-organisms from the point of view of the biologist, and records their behaviour under every conceivable test. It is work in this physiological direction which is doing so much to elucidate the nature of disease, and until the same spirit is applied to the whole domain of pathology the latter will be incomplete. We know no more about a disease by ascertaining its morbid anatomy only than we know about a bacterium by mere familiarity with its morphology. Useful up to a certain point, such knowledge is of value to us in the separation of diseases, but tells us little of their essential nature. And, as far as cholera is concerned, although many have believed that they found the living entity peculiar to it, not one of Koch's forerunners has carried the question so far as he has done, and studied this "germ" in all its life-relations. So thoroughly has this been done by Koch that it will require demonstrations as searching and as thorough to prove that he has not been on the right track, but has been pursuing an *ignis fatuus*. Nothing to our mind is more striking than the remarkable reception which his researches have met with, not only among leading German pathologists and physicians, but even in France, where the bias was till lately quite the other way. All this enhances the interest with which we shall look forward to the approaching inquiry in India, although there, too, we doubt not, are to be found men like Dr. Vandyke Carter, who can weigh and appreciate the evidence adduced by Koch, and who are not blinded by prejudice or enchained by preconceived ideas.

ISOLATION ARRANGEMENTS AT BRISTOL.

THE renewed discussions which have taken place at Bristol as to the question of isolation for infectious diseases, and especially the manner in which the subject was dealt with by the urban sanitary authority, show clearly that Bristol fails to understand the important position which adequate means of isolation hold in the sanitary defences of the community. Some of the opinions which were expressed by the medical officer of health are also, in our opinion, but little calculated to set this question on a proper footing. Thus, Dr. Davies is reported as having expressed the opinion that large hospitals containing typhus and other fevers were, from a sanitary point of view, a great evil. Now, it is difficult to understand how such an infectious hospital as Bristol needs can, under ordinarily efficient control, become a danger; and, apart from the question of small-pox, all experience of such hospitals in England is entirely opposed to this view. The details given in Dr. Thorne Thorne's official report to the Local Government Board as to the influence of the London Fever Hospital, where some thousands of cases of typhus, relapsing fever, typhoid fever, and scarlet fever were under treatment, are a striking answer to the contention maintained at Bristol. Then again, Dr. Davies would not receive a patient into the hospital belonging to the sanitary authority unless he had a guarantee that payment would be forthcoming; and, at the same time, he would refuse admission unless he could assure himself that his action would go towards diminishing centres of infection in the city. In other words, work, which is admittedly carried out for the benefit of the community, is to be paid for by the individual who, in the interests of others, submits to isolation; and this in a building which has been erected and is maintained out of the public rates. Such views will, we believe, before long be altogether of the past, and sanitary authorities will come to see that it is as much to the public advantage to remove centres of infection from their midst at the public cost as it is to use the public funds in order to get rid of accumulations of refuse from amongst the community generally. Indeed, many authorities already take this common-sense view of the question, and the result is that they succeed where Bristol fails. The mere bargaining as to expenses has over and over again defeated its object; for, whilst waiting to know where the few pounds were to come from which would defray the cost of the isolation of cases of fever, the disease has spread, and whole families have been thrown on the rates. In every sanitary hospital there should be one uniform sort of accommodation open to all free of cost, and where possible a small amount of superior accommodation should be maintained for those who seek some measure of privacy, and who are able and willing to pay for it. The low social status of a patient forms no criterion as to the extent to which he or she may endanger public health, and it is often far more important, in the interests of a community, to secure the instant isolation of respectable people from dairies, hotels, and houses of business than it is to remove the sick from a labourer's cottage.

PAYING PATIENTS AT ST. THOMAS'S HOSPITAL.

A WRITER in *The Times* depicts in glowing colours the advantages of St. Thomas's Hospital as a place for paying patients. We cannot quite share the satisfaction. The wards of hospitals are, as a rule, meant for the poor, and, from this point of view, every case of the kind described by the correspondent of *The Times* means the exclusion of a poor person who cannot afford to pay. We are not denying the utility of hospitals in certain cases for persons who can pay, nor do we forget that there are circumstances attending St. Thomas's which do not obtain with other general hospitals. But we hold that where cases can be treated equally well at home, home is the best place for them. There is need of care, in the interest of the poor, that the great hospitals be not wrested from them. It may be very satisfactory to the writer of the letter to have had a "very expensive operation" performed, and subsequent attendance, at the rate of nine shillings a day, including operation, food, nursing, and medical attendance; but it would be necessary to know much more of his circumstances to be able to justify such a use of the hospital, or such an under-payment of medical services.

HEALTH AND HOLIDAY RESORTS COMPETITION.

THE competition for public favour among health and holiday resorts is keen, and in so far as it induces a laudable desire for favourable health reports, is not altogether without public advantage. Our attention has, however, been called to an endeavour to "influence" local mortality statistics in a way that cannot be approved, and which might easily lead to most mischievous results. A circular letter has recently been issued to all the medical practitioners of Southport, signed by the medical officer of health for the borough, and by the chairman of the Health Committee, also a medical practitioner, calling their attention to the "desirability of limiting as far as possible the certification as deaths from 'diarrhœa' to those cases which are strictly and undoubtedly zymotic in their nature." Bearing in mind that the causation of infantile diarrhœa is still the subject of an extended Local Government inquiry, and that much difference of opinion prevails as to its zymotic origin, it is easy to guess that if the Southport practitioners respond to the invitation of Dr. Vernon and Mr. Pilkington, the result will be a remarkable decline in the death-rate from infantile diarrhœa in that borough during the present season. The circular concludes with the following sentence: "Believing that you are as anxious for the credit and repute of the borough as ourselves, we have ven-

Digitized by Google

tured to place this matter before you." The intention would seem to be to steal a march upon other health resorts by preparing the way for a low death-rate from summer diarrhœa in Southport. We must, however, enter a strong protest against any such local attempt to influence or limit the discretion of medical practitioners in the certification of causes of death; and we think that, on further consideration, the sanitary authorities of Southport will admit that their zeal for the "credit and repute of the borough" outran their discretion in the issue of this circular.

DAIRY SCHOOLS.

MUCH good ought to be effected by the establishment of a system of dairy schools, which is now under the consideration of the Dairy Conference Association, and of which Lord Vernon's school at Sudbury is the type and pioneer. There are many ways in which educational method may aid the perfection of the milk industry. The manufacture of butter and cheese, for example, presents a field of enterprise capable of rewarding a wider and higher degree of cultivation than it has yet received. This is probably even more the case with the largely pastoral countries of Scotland, Ireland, and Wales than with England. If the introduction of system into dairy training should help to develop this branch of industry, something will have been done towards the settlement of the social and sanitary question, How to find for poor as well as rich butter at once pure, wholesome, and cheap. Another matter which may well form a subject of instruction is the clean and healthy housing of cattle, with the equally important consideration of the kind of food best suited for nourishment of the animals and for milk production. One hears perhaps too little of the employment of other animals besides cows for dairy purposes. In the interest of invalids and children, though not of these only, it is to be hoped that the promotors of this scheme may have time to turn their inquiries in this direction.

THE RECENT REVELATIONS AT ALNWICK.

THE conditions associated with a death from English cholera at Alnwick in Northumberland, as revealed at a coroner's inquest, certainly call for the term "scandalous" which has been locally applied to them. The actual conditions of filth under which the death occurred are not the most important feature in the revelation that was made, for they might either have been accidental or have escaped detection. But when the medical officer of health and the inspector of nuisances are, in their evidence, compelled to admit that the reports on the sanitary state of the town and of the disgusting conditions of housing [illegible] brought before the local board are almost habitually ignored, and when this admission is supported by details which are simply revolting, the sanitary administration to which the town is subject is placed in a very discreditable position. Thus in Shield-yard a room was found in which there were two standing beds, two shake-downs, an old table, and a form. Inhabiting the room were five men, three unmarried women, and two children. On a straw mattress on the floor were lying a man and a woman, and two men on another mattress. Two men, one woman, and two children occupied one standing bed; the keeper of the lodging slept in the other. The room measured about 10 ft. by 16 ft. by 7 ft.; it was dirty and dark, with no ventilation, and in the centre was a pan containing human excrement. These conditions, it appears, had often been brought under the notice of the authority, and yet they still remained. Such is an example of the sanitary administration to which Alnwick is subject, and it is to be hoped that at the next election the ratepayers will remember that the real responsibility lies with themselves, for they choose their own representatives to govern them. The coroner, in summing up, declared that the inquest had exposed a scandalous state of affairs in the town. The case is well deserving of the attention of the Local Government Board.

THE INDIAN CHOLERA COMMISSION.

SOME surprise has been expressed in India that the Government have appointed Dr. D. D. Cunningham and Dr. J. J. Cuningham to the cholera commission. It is feared that the last-named gentleman, who, in his capacity as Sanitary Commissioner, has written much on the subject, may be too much hampered in his research by his well-known views of the nature of the disease (he has strongly upheld the non-contagious theory) to be entrusted with this new inquiry. We hardly reciprocate these fears; feeling assured that the inquiry will be conducted upon a strictly scientific plan, and that the conclusions arrived at will be drawn up with a sense of responsibility which should neutralise any of the effects of personal preference for a particular hypothesis.

CRUELTY TO GOATS AND DONKEYS AT THE SEASIDE.

No one who has taken the trouble to look carefully at the goats and donkeys employed in drawing children's carriages or bearing on their backs heavy burdens of troublesome and irritable humanity, at the seaside in the spring and summer seasons, will need to be reminded that these animals are the subjects and victims of much needless and wanton cruelty. We are glad to see that the case of the "goats" has attracted attention of late. We venture to hope it will not be long before the poor donkeys are pitied and protected.

GOOD NEWS FOR MAN AND BEAST.

THERE are few societies more benevolent in their design and operation than the Metropolitan Drinking Fountain and Cattle Trough Association. In such a droughty summer as this it is pleasant to bring its claims under the notice of our readers. To say nothing of work in progress or preparation, the twenty-fifth annual report is able to announce the erection of fifty-two new troughs for animals and fifty-one new fountains for human beings. Most of the structures of the Society are examined and cleaned by its servants three times a week.

CHOLERAIC MICROSCOPY.

THE late Professor Filippo Pacini has left records of a series of original microscopic observations on cholera, which are in course of publication by Vallardi of Milan, under the editorship of Dr. Aurelio Bianchi. It will be very interesting to compare with Professor Koch's, the observations of one so eminent in histology as the discoverer of the Pacinian bodies.

THE DEATH OF A MIDGET.

THE papers contain accounts of a poor diminutive baby that was let out by its mother in Birmingham for 30s. a week for a show. It was but six weeks old, nine inches long, and weighed only ten ounces. The child was exhibited every five minutes, with an interval for dinner and tea. When the mother was sober she suckled the child; when otherwise, as she usually was, it was fed on scalded biscuits. On Sunday convulsions came on, and in the course of a drive the day after, meant to revive the child so as to enable it to go on show to Nottingham, it was unkind enough to die. The wretched mother expressed her regret to the coroner that she had not sold the child, after death, for £20, as she might have done but for scruples about the law! She was severely

Digitized by Google

reprimanded by the deputy coroner, and not one whit too severely. But it strikes us as a great omission that no censure was passed on the showman, who was scarcely, if indeed at all, less culpable than the debased and unnatural mother.

IN the *Indian Medical Journal* of July, Dr. P. Cullen gives a table of thirty-eight cases of leprosy, setting forth age, sex, occupation, family history, &c., of the sufferers. Asiatics, as a rule, do not believe in communication of the disease by personal contact, but are highly suspicious of food which has been handled by a leper. In no case out of the thirty-eight were the living children of the lepers affected with leprosy, and in only four cases was admission made of the disease being present in the parents or grand-parents, thus far indicating the absence of heredity in the causation of the malady.

THE honour of knighthood has just been conferred upon Dr. William Carter Hoffmeister, Surgeon-Apothecary to the Queen at Osborne. Dr. Hoffmeister obtained the degree of M.D. at the University of Glasgow in 1840, the diploma of Fellow of the Royal College of Surgeons in 1855, his membership diploma bearing date 1840, and the licence of the Royal College of Physicians of London in 1861. He is Honorary Consulting Physician to the Royal Isle of Wight Infirmary, and Surgeon to the Royal Yacht Squadron.

FROM the report of the examination made by Colonel Sir Francis Bolton, C.E., of the water supplied by the several metropolitan water companies during the month of July, it appears that the Thames water was of about the same average quality as in the previous month, being again, for river water, remarkably free from organic matter. The water drawn from the Lea exhibited some improvement on the previous month's samples.

SURGEON T. K. ROGERS, Professor of Chemistry, Madras Medical College, and Chemical Examiner to the Government of Madras, died of typhoid fever on June 12th. He entered the service in 1877.

REPORT through Russian sources states that the "plague" at Bagdad is subsiding. Quarantine regulations are, however, still in force.

THE BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.

No. III.

BACTERIA ASSOCIATED WITH DISEASE IN MAN.

SPIRILLUM OF RELAPSING FEVER.

(*Spirochæte Obermeieri.*)

These are the threads, having a spiral form, (Fig. 9.) In length they usually measure from 16 to 40 μ. When alive they progress rapidly, and an undulatory movement may be seen passing from one end of the thread to the other. They occur in the blood of patients affected with recurrent fever, during the onset of the attacks, but are not found in the intervals. They cannot be cultivated in the usual manner, but the threads retain their mobility for a long time in blood serum and in half per cent. salt solution. Blood containing the spirilla, inoculated into monkeys, causes them to become affected with relapsing fever, and the blood of an animal killed at the height of an attack is found to contain the organisms in abundance.

BACILLUS OF MALIGNANT ŒDEMA.

(*Vibrion septique* of Pasteur.)

This is a rod-shaped bacillus (Fig. 10), which varies considerably in length, reaching 3·5 μ. The breadth is 1 to 1·1 μ.

FIG. 9.

FIG. 10.

FIG. 9.—Spirilla from the blood in a case of relapsing fever. Objective $\frac{1}{5}$ in.

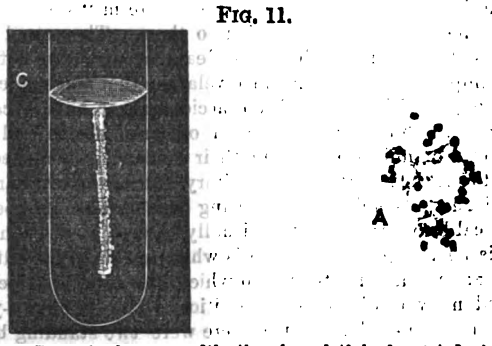

FIG. 10.—Bacilli of malignant œdema in the œdematous fluid. The nuclei of two pus corpuscles are represented. Objective $\frac{1}{5}$ in.

They often lie in chains of two or more bacilli, and are found also as long threads, in which no jointing is observable. They are distinguished from the anthrax bacillus by their smaller breadth and their less abruptly truncated ends; they are, moreover, frequently motile. This bacillus is widely distributed, and occurs, among other places, in the upper layers of cultivated ground. When such earth is placed beneath the skin of a guinea-pig it frequently happens that extensive subcutaneous œdema occurs, and the animal dies in the course of twenty-four to forty-eight hours. The bacilli are then found abundantly in the œdematous fluid and in the lymph of the different organs, though they do not appear in the blood of the heart for some time after death. The same phenomena appear when a considerable quantity of the œdematous fluid is injected beneath the skin of another animal. The bacillus is one of the "anærobien" whose growth is hindered by the presence of oxygen. It is cultivated with difficulty outside the body, and then only without free access of oxygen. Injection of the cultivations again gives rise to the symptoms of the disease.

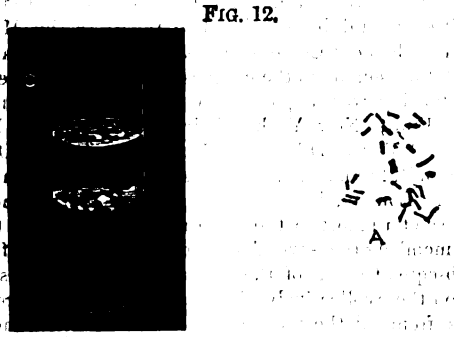
BACTERIUM LACTIS.

This is an actively moving oval bacillus (Fig. 11), which exists in milk in great numbers. When isolated and cultivated in gelatinised meat infusion (Fig. 11, c) it forms a rather

FIG. 11.

A, Bacteria from a cultivation in gelatinised meat infusion. Objective $\frac{1}{5}$ in. C, Test-tube cultivation.

slender white growth along the track of the inoculating needle, but spreads on the surface of the gelatinised mass, forming a thin transparent expansion. When a small quantity of such a cultivation is inoculated into a flask of milk which has been plugged with cotton-wool and sterilised, the milk "turns sour," the milk sugar is converted into lactic acid, and curds and whey are formed in the usual manner. The milk so altered remains without undergoing any further change.



BACILLUS BUTYRICUS.

This bacillus (Fig. 12) is about 3 to 10 μ long and less than 1 μ broad. It often occurs in chains, and sometimes as long, apparently, conjoined threads which exhibit active move-

Digitized by Google

ment. In solutions of starch, dextrin, and sugar it sets up a fermentation with the production of butyric acid, carbonic oxide, and hydrogen. The process of spore formation takes place as follows:—The bacilli become shorter and increase in breadth up to 2·6 μ. In the shorter rods this widening takes place in the middle, in the longer at one end. At the same time the protoplasmic contents become more highly refractive, and the limiting membrane thickens. The spores are set free by dissolution of the membrane of the mother

FIG. 12.

a, Bacilli from a cultivation. Objective $\frac{1}{16}$ in. c, Test-tube cultivation.

cell. They are ovoid bodies, measuring 2–2·5 μ long and 1 μ broad. When they germinate, the double contour of the spore disappears at one end, and the contents grow out into a bacillus. The young bacilli may often be seen with the empty spore membrane attached to one end. The bacillus may be cultivated in gelatinised meat infusion (Fig. 12, c.), and causes it to become liquid. The bacilli fall to the bottom of the liquid part, but a white scum is formed at the surface.

MILK MICROCOCCUS.

This is a small micrococcus (Fig. 13), frequently found in milk. So far as has yet been discovered, it produces no fermentative change in it. It may be cultivated in gelatin-

FIG. 13.

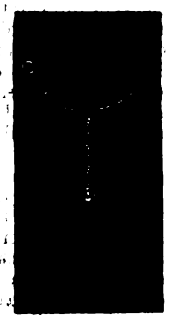


FIG. 14.

FIG. 13.—A micrococcus commonly found in milk. A, Micrococci from a cultivation. Objective $\frac{1}{16}$ in. c, Test-tube cultivation.

FIG. 14.—A, Bacilli from a cultivation. Objective $\frac{1}{16}$ in. c, Test-tube cultivation. The appearance beneath the surface expansion is to indicate the deep smoky-brown colour induced in the gelatinised infusion by the growth of the organism.

ised meat infusion (Fig. 13, c), and forms small round white balls along the track of the inoculating needle, but no surface expansion.

BACILLUS OF BLUE MILK.

Milk which is turning sour is sometimes observed to become blue, the extent to which it does so varying greatly at different times and different places. This change is due to a rod-shaped bacillus (Fig. 14, A). When cultivated in gelatinised meat infusion (Fig. 14, c), it forms a very slender growth along the course of the inoculating needle, and spreads on the surface after the manner of the bacterium lactis. The infusion on which it grows undergoes a remarkable change of colour, a change which extends far beyond the limits of the growth itself. The colour is a deep smoky-brown when seen with transmitted light.

THE INTERNATIONAL HEALTH EXHIBITION.

GERMANY AND AUSTRIA.

THE sister court to that occupied by the French section contains the exhibits of Austria, Germany, and Italy. These in many respects are attractive and interesting, but they suggest a general rather than a special exhibition. Lobmeyer's hand-painted glass from Austria; the art pipes and cigarette-holders, some of them carved by mere children, shown by Raunegger of Vienna; the German potteries of the Neuremberg type; Adarneck's soap, moulded and painted so as to resemble clusters of luscious fruit; the Italian filigree jewellery; the Florentine mosaics,—these and many other objects are deserving of admiration, but are not closely connected with the preservation of health. The Germans, however, show some inventions which have met with much approbation among continental hygienists: notably, Schomburg's spark and soot arresting apparatus, and Trentler and Schwarz's "Aërophor." The latter has received in England the greatest of all homage—imitation. This is an apparatus placed within an ornamental column which pumps air out of or into a room according to the manner in which the fan is made to rotate. The motive power is a small jet of water under slight pressure. A pulveriser is provided by which moisture or scented and medicated aromas may be mixed with the air. The smallest-sized apparatus will pump into a room 1800 cubic metres of air in an hour, at an expenditure of 0·35 metres of water. This is the invention which at the Berlin Health Exhibition took the only and highest award given for ventilation. Some English manufacturers have similar but not such complete methods, nor have they been so scientifically worked out.

Immediately opposite this ventilator are the ingenious contrivances devised by Dr. Ernest Sandow, of Hamburg, which he proposes to use both for the prevention of infection and for the treatment of infectious cases. For instance, there is a bed surrounded by curtains of a waterproof material to render them air-tight. At the foot of the bed is a box containing some felt and wool to filter the air, which can only gain admittance at this point; while at the other extremity a clockwork apparatus causes a revolving fan to draw out the air at the rate of forty to sixty feet per minute. If the case be infectious, the air drawn from the bed is conveyed by a flue underneath a stove, where it is burnt before being discharged into a chimney. Perambulators and carriages are similarly enclosed and ventilated, so that patients may enjoy the air of the street without having to breathe the dust, dirt, and floating matter which render town air especially dangerous, and which is arrested by filtering through felt. Dr. Sandow has also the happy idea of covering the stretchers or ambulances used for conveying patients to the fever hospital in such a manner as to allow no air to escape save that drawn by the clockwork ventilator through a filtering and disinfecting medium. Thus one of the principal objections to transporting fever patients to the hospital may be overcome. All these contrivances are susceptible of very wide application, and we should like to see some experiments made with respect to the ventilating powers of the clockwork machinery.

The improved adjustable scholars' desks, manufactured by the celebrated Berlin firm, H. Simon and Co., are to be found alongside Dr. Sandow's exhibits. This firm has taken a leading part in seeking to initiate reform in school furniture, which it designs after models calculated to prevent deformity among children. The desks shown are adjustable to the height of children of the age of six to sixteen years. The lower portion can be turned up so as to hold books and prevent stooping while reading, and the seat is so contrived as to keep the spine in its proper position. The fact that the Duke of Edinburgh has purchased some of these desks for his own family will, we hope, encourage the use of furniture constructed to harmonise with the laws of human anatomy.

Schomburg's spark and soot arresting apparatus is a somewhat complicated form of chimney-cowl, and cannot be easily described, but as it is widely used in Germany, is patronised by the Government, and adopted by the German navy, it should be carefully examined. The apparatus consists of a metallic box and chimney, to be placed on the roof of buildings or on the decks of ships. There is a circular brush and weight

Digitized by Google

attached, which when let down sweeps automatically the chimney. The smoke on ascending strikes a spiral division, which throws the soot into a box; while the smoke escapes into the air. The action of lowering the brush opens the soot-box, thus letting out at cleaning time what has been collected in it. The system has the extra advantage of preventing the escape of sparks from the chimneys, thus reducing the risks of fire.

Most of the other German exhibits relate to the creature comforts, not least among these being the Berlin automatic ash tray; this at once extinguishes and hides from sight the tips of cigars and cigarettes, which cause by far the larger share of the nuisance due to smoking. There are, of course, some German wines and beer; but those reformers who connect the cause of temperance with hygiene will be especially interested in the Weissbier, which, though brewed from wheat, malt, and hops, is a non-intoxicating beverage. It should be sold at a very cheap rate, and would then constitute a popular nutritive drink. Perhaps Hermann Stibbe's elaborate array of liqueurs is also as nearly connected with the cause of temperance. Alcoholic excesses must destroy the power of appreciating the varied and refined flavours of maraschino, crème de theine, and Dutch curacao; thus we always find these delicacies to be best appreciated among essentially temperate people. In England the consumption of liqueurs is very limited, a consequence probably of the exorbitant prices charged. In this case, however, the prices quoted are exceptionally moderate, a result attained by the establishment of a branch manufactory at Cologne, which enables this old Amsterdam firm to avoid the heavy Dutch duties on alcohol. We have tasted these liqueurs, which are now imported into the English market, and find that cheapness does not detract from their body and flavour. There are also some celebrated German mineral waters exhibited, notably the Juliushall, an effervescing water that is very similar to though cheaper than Apollinaris, and is highly recommended for its digestive qualities. These waters are sold in London.

Mingled with the exhibits of Germany are those of Austria—to be recommended, however, for their gastronomic and artistic excellence rather than for their direct connexion with sanitation. There are, for instance, the Austrian mineral waters from the alkaline and acidulous spring of Giesshübler; and the digestive and flavouring Paprika (capsicum annum), which, in various degrees of strength and pungency, may be considered as the Hungarian curry. Samples from the shiploads of prunes from Bosnia and Turkey that are sold in England as French prunes are also shown here by Markó and Weyden of Budapest. There may also be seen the curious honey-cakes popular in Central Europe, and a "nectar" liqueur which professes to work wonders. This is an alcohol flavoured with the extract of ten different herbs, including camomile, vermouth, ginger, black pepper, vanilla, &c. But the exhibits that will be most welcome to the traveller and connoisseur are the celebrated Hungarian wines of the Château Palugyay, near Presburg. These have now been introduced into the English market by Messrs. Josaphat and Co., and merit special notice, for by reason of their purity and moderate price they may well compete with the French wines. In these wines there is much choice and variety; there are the Château Palugyay hocks, Karlowitzer, and some exquisite Tokay. Among the less known wines we would recommend the Ofneradelsberger as a rough, strong, nutritious wine, apparently free from too much sugar, and containing probably a large proportion of iron and tannin. The Château Palugyay claret has a soft, round flavour that will suit the English palate; while, for medical purposes, the Tokay Szamorodny and the Adelsberger may be recommended. Most of these wines are cheap; and, from a sanitary point of view, all cheap pure wines should be welcome, as tending to fortify the system and to check intemperance by engendering refined tastes.

In conclusion, we should mention Haus Denk's patent cross-stitch print, which will save the eyesight of the thousands of children employed in Central Europe to ornament table-linen by coloured embroidery. The counting of stitches is avoided by this method, and much economy of time and visual power realised.

VACCINATION GRANT.—Mr. T. H. Tidswell, of Morecambe, has received the Government grant for successful vaccination (third time).

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

(From our own Correspondent.)

AMONGST the papers read on Monday, August 11th, that by Professor Austin Flint from New York, in the Section of Medicine, was one of the most interesting. At the meeting of the last Congress in London, 1881, it was resolved that a committee should be appointed to report to the Medicine Section of the next Congress on a uniform nomenclature of auscultatory sounds in the diagnosis of diseases of the chest. The following were appointed members of this committee: Austin Flint, New York (chairman); Professor Ewald, Berlin; Professor D'Espine, Geneva; and Drs. Douglas Powell and Mahomed, London. At a meeting of this committee in London, it was agreed that each of its members should send a report to the chairman, who engaged to send to the members the several reports or an abstract of them, the subsequent report of the chairman to the Congress to be based on these collectively. Professor Flint had now received reports from all the members of the committee and from them he had made the accompanying tabulated lists. Professor Flint concluded his paper by laying stress upon the great international importance of a uniform nomenclature. The work had been very difficult for the members of of the committee, and they would be glad to have suggestions from the medical profession. In the discussion that followed Professor Ewald, Dr. Mahomed, and Dr. Acland took part. Professor Ewald called attention to the great difficulty of the question, of which the lists ought to be considered only provisionary, but he hoped that an addition to the number of the committee would make its solution easier.

In the Section of Surgery it was expected that Sir Joseph Lister would read the first paper, but that gentleman was not present. Professors Esmarch, Trélat, and Verneuil read papers on the Operative Treatment in Malignant Diseases of the Rectum.

The Section of State Medicine was that most numerously attended on Monday, Professor Tommasi Crudeli, from Rome, reading a paper on Asiatic Cholera.

At the general meeting on Tuesday, Professor Crudeli read an interesting paper on Malaria. After apologising for using the word "malaria," instead of the more strictly scientific term, as the title of his paper, he proceeded to combat the theories which ascribed malaria to telluric causes. That idea was, he said, entirely false, as had been proved by various observers; nevertheless, the nature of the soil had much to do with the development of the disease. The term "malaria" had long been associated with the theory of a ferment independent of the soil. The nature of this ferment had not been definitely ascertained, and many theories had been formed with regard to it. Some observers were of opinion that it originated in a living contagion, which appeared only under special circumstances. Others sought it amongst different water-plants, and whole series of seaweeds have been described as the conductors of the disease. In his opinion, however, the enemy was a living ferment, the representative of a parasitic organism, the peculiarities of which he further described. Its development depended upon certain conditions—viz., (1) a temperature of more than 20° Celsius, (2) a soil favourable to the reception of the organisms, and (3) the influence of the atmospheric oxygen upon the soil. With regard to the effect of temperature, Crudeli laid stress upon the fact that the health of the inhabitants of malarious districts improved during the winter, but that a sudden rise of temperature was frequently accompanied by an outbreak of the disease. It was of course impossible to reduce the temperature by artificial means, but it was possible to improve the state of the soil. With this view drainage and canalisation had been proposed, by which means the subsoil was drained and the escape of the surface-water facilitated. Anchisi, in the last century, propounded the theory that malaria could be prevented by planting trees. He (Crudeli) had but little faith in this method, and in support of his opinion adduced the fact that eucalyptus trees had been planted in the Roman Campagna, and had given great hope, until, in 1882, malaria broke out in that part, whilst other malarious districts had remained free from disease. Nevertheless, these means should not be neglected.

Digitized by Google

The object should be to make the soil sterile for malaria without robbing it of its fertility; a thorough cultivation of the soil was to be highly recommended. The principle, however, which, in combating malaria, it was most important to keep in view, was that by promoting the general health the disease might be kept at bay. Many experiments had been made in this direction with quinine and eucalyptus preparations, Bosnia experiments had been made upon sixty-seven individuals, and had been attended with happy results. Of course, the use of arsenic required much caution, as it was not desirable that the population should become arsenic eaters. His experiments were, however, far from being concluded. Moreover, they met with considerable opposition, as patients often objected to taking sufficiently large doses of the drug. In

but as yet none had proved satisfactory. Certain experiments which the speaker had made with arsenic had yielded good results, and these experiments were now being conducted on a larger scale. They had been commenced in the beginning of 1882, and had been continued last year and this year. As a rule for the treatment by arsenic, he pointed out that it must be commenced before the malarial season sets in, and the doses must be gradually increased. In conclusion, Crudeli pointed out the great advantage of high and airy sleeping places. He reminded his audience of the facts that the Greeks slept on the roofs of their houses, that in malarious districts the inhabitants often used the lofty monuments as sleeping apartments, and that the engineers of the Panama Canal slung their hammocks high up between two bamboo poles.

Dr. Verneuil of Paris then spoke on the Neoplastic Dia-

Digitized by Google

thesis, after which Dr. Billings of Washington presented the Congress with the following invitation :—

"In behalf of the medical profession of the United States, we, the undersigned members of a committee appointed for that purpose by the American Medical Association, have the honour to offer to the International Medical Congress an invitation to hold its next meeting in the City of Washington in September, 1887.

"AUSTIN FLINT.	GEO. J. ENGELMANN.
JERVOIS A. SAYRE.	F. M. BROWNE.
CHRISTOPHER JOHNSTON.	JOHN S. BILLINGS."

The most interesting event in the sections on Tuesday, the 12th, was Dr. Sayre's demonstration of his plaster-of-Paris jacket, and the exhibition of three leprous patients by Dr. Hansen from Bergen in Norway.

Wednesday, August the 13th, was almost entirely devoted to pleasure, the reception committee having arranged an excursion to Elsinore for the members of the Congress and their ladies. At 10 A.M. five large steamers left Copenhagen with about two thousand persons on board, and reached Elsinore at midday. Here luncheon was prepared in the ancient fortress of Kronborg; after partaking of which the guests visited the various points of interest in the neighbourhood. At 4 P.M. three long trains left Elsinore for Copenhagen, but part of the company stopped on the way to visit the beautiful Castle of Fredricksborg. In the evening, before a large audience, Professor Esmarch read his paper on Samaritan Schools.

On Thursday, the 14th, Sir William Gull read a paper on the International Collective Investigation of Disease, a report of which has already been published in our columns. The speech was received with great enthusiasm. Sir Henry Acland, the president, proposed a vote of thanks to Sir William, and laid great stress upon the importance of the matter in hand. The whole meeting then rose to express their appreciation of the address, which was remarkable not only for its practical and theoretical importance, but for the elegance and ease of its style. Sir James Paget seconded the motion, which was supported by Professors Ewald, Bouchard, and Billings, and carried unanimously.

The following Committee was then elected :—Professors Trier and Lange for Denmark; Professor Bull (Christiania), for Norway and Sweden; Professor Rauchfuss (St. Petersburg), for Russia; Professors Schnitzler (Vienna) and Pribram (Prague), for Austria; Professor D'Espine (Geneva), for Switzerland; Professors Ewald and Bernhardt (Berlin), for Germany; Professors Bouchard (Paris) and Lepine (Lyons), for France; Professor Jacobi (New York) and Dr. Daries (Philadelphia), for the United States; Sir Wm. Gull, Professor Humphry, and Dr. Mahomed, for Great Britain; and Sir Joseph Fayrer, for India. The representatives of Greece, Italy, Spain, German Switzerland, Holland, Belgium, Cuba, and Japan are still to be elected. Dr. Isambard Owen (London) was appointed General Secretary.

Prof. Panum, the Danish president, then said, "The importance of the resolution passed at this meeting is so great that this International Congress has perhaps the distinguished honour to open a new epoch in medical history. We to-day send into the world the basis of the most important investigations, only to be obtained by the co-operation of all civilised nations. At the same time that I congratulate our Congress on the resolution of to-day, I will express the hope that this new committee, which will girt the world, may be productive of happy results, and continue a blessing to humanity and a benefit to science."

(To be concluded.)

THE FIFTH INTERNATIONAL CONGRESS OF HYGIENE.

(From our own Correspondent.)

FAVOURED by the most exceptional and splendid weather, the Sanitary Congress met under favourable auspices, though the recent death of the Prince of Orange necessarily threw a certain chill on the proceedings. All who spoke in the name of Holland had to deplore this national loss. Nor was this all. Death and disease had been active in the ranks of the organisers of the Congress. Sir G. J. G. Klerck, formerly a member of the Dutch Government, who had promised to act as president, died last January, and two of the vice-presidents were afflicted with severe illness. There are not so many members as at Geneva two years ago, though I have counted 212, including undoubtedly the most eminent sanitary authorities of France and Holland, and many distinguished reformers from twenty-one different nationalities. Many governments, municipalities, and learned societies have sent their delegates. But, as usual, England is more feebly represented than any other nation. We have, it is true, Dr. Corfield with us, and he is a host in himself; but in spite of distance, there are a greater number of members present from the United States than from England. Yet as England is the most prominent among European nations in carrying out practically the laws of hygiene, it should not only be represented by a powerful delegation, but the Congress should have been held in London, and during the Health Exhibition.

The proceedings commenced on Thursday afternoon, the the 21st inst., the Congress being opened by its President, Dr. de Beaufort, Senator. His speech was simple and cordial; he apologised for the absence of illuminations, for the quiet character of the reception, on account of the national mourning. But he not only promised a sympathetic reception, he declared that the Dutch people would not fail to take an intelligent interest in the proceedings of the Congress. (The Dutch newspapers have given full accounts of the debates.) Dr. de Beaufort was very sanguine as to the adoption by legislature of the discoveries of science, and thought that those pessimists who described this as an age of decadence were altogether in the wrong. When we saw doctors devoting themselves, heart and soul, to the development of those sanitary measures which were best calculated to reduce the number of their patients, we could not doubt the disinterested nature of their sentiments. Then there were those heroic scientific expeditions to the borders of the Ganges, and other places where epidemics were raging, that will not fail to elicit the admiration of future generations. In spite, however, of all these efforts, the cholera had invaded France; but union and mutual consultation would strengthen action, and the Congress might be described as a council of war held to combat the cholera. The members would meet in the ancient hall where the Dutch Senate held its sittings. On the roof, painted in the sixteenth century, when the Dutch Republic was in the zenith of its prosperity, we might see the civilised world gathered together to render homage to the greatness of Holland. This painting might serve as an emblem for the Congress, which had brought together representatives from all parts of the world to render homage to the great cause of humanity, the preservation of public health.

The general secretary, Dr. Van Overbeek de Meijer, who has had all the hard work and drudgery incident to the organisation of the Congress, then spoke and showed the difficulties that had to be overcome. The outbreak of cholera rendered the holding of the Congress a questionable matter; but with the approval of the French sanitary societies it was ultimately decided that a great international movement could not be checked by an epidemic in a mere corner of Europe. He denounced internal quarantines as vexatious and useless. After rendering homage to the doctors who bravely fought the epidemic and sought to check its development, he quoted the motto of the Prince of Orange, "*Je maintiendrai*," and of Holland, "Union is Strength." The Congress would also seek its strength in union, and against ignorance would maintain and propagate the knowledge and teachings of hygiene.

Dr. Corradi, of Pavia, recalled how Holland and Italy had been in the vanguard of civilisation, especially in respect to the medical sciences; and Dr. Caro, in the name of the Spanish Government, also returned thanks.

The real business of the Congress began on the morrow, when all the five sections met. It would, however, be impossible to describe even briefly the proceedings of all these groups. Each section meets five times, and for two hours, so that this represents twenty hours of close debate, not to mention the lectures delivered each afternoon. In the evening of the first day a brilliant reception was given to the members of the Congress by the municipality of Amsterdam at the Palace of the Arts and Sciences. The Burgomaster delivered a speech of welcome, and one of the best military bands discoursed sweet music. On the Friday there was an open air concert in the Zoological Gardens of the town and a soirée at one of the hotels, while on Saturday another concert was held at the pavilion of the literary club, in the celebrated wood which is one of the attractions of the Hague.

Digitized by Google

But the Sunday's excursion to Rotterdam, Feyenoord, Dordrecht, and Moerdijk was undoubtedly the most pleasurable event. The greater part of the day was spent on a steamer in contemplation of the dykes, the towns, and the marvellous industry of the Dutch people. The remaining three nights of the Congress are to be devoted to receptions and manifestations of hospitable welcome. In spite of all this much serious work has been done, and a fierce battle is now being waged on the question of quarantines. As a final result has not yet been attained, it will be necessary to postpone the analysis of the proceedings, for they will not be without influence on the various continental Governments who have sent special delegates to the Hague.

The Hague, August 25th, 1884.

CHOLERA AND QUARANTINE.

So far as Marseilles and Toulon are concerned, the reduced cholera mortality remains much at a standstill, the deaths at Marseilles varying from some six to ten, and those at Toulon from some two to four a day. A few fresh localities continue to receive infection in the south of France, but in no place does the disease make headway, and it is to be hoped that, although the subsidence of the epidemic is but slow, yet that it will soon be complete. Unfortunately, however, the extension to Italy has assumed serious proportions. At the commencement of August several of the northern provinces became infected, those of Cuneo, Bergamo, Turin, and Massa Carrara exhibiting as the month went on the largest number of attacks. Campo Basso, further south, was next attacked. Suddenly the disease took a further leap; it was asserted that suspicious cases had occurred at Naples, and then genuine attacks were reported from the neighbouring province of Cosenza. But it is in the north that the extension has been most severe, and during the past few days the epidemic has assumed very serious proportions both at Busca and Spezzia, in which places fifty-eight and eighty-four deaths respectively had occurred up to August 25th. But it is doubtful whether even this represents the real magnitude of the outbreak, for it seems clear that secrecy was maintained by the officials until it was no longer possible. The Italian Government are still seeking to control the diffusion of the infection by means of sanitary cordons and fumigations, and some thousands of troops are now engaged in an endeavour to effect the desired object. But even in Italy a strong feeling is beginning to show itself against the quarantine regulations as at present carried out. So long as they mainly affected foreigners all went fairly well, but now that the Italians themselves are suffering both from the actual nature of the restrictions and also in their commercial relations, a feeling of opposition is manifesting itself. Milan, it is said, is taking the lead in an agitation against measures which, whilst interfering with freedom of movement both of persons and of goods, have been ineffectual in so far as their professed purpose is concerned; and it is also believed that some members of the Ministry are beginning to doubt the value of the existing practice.

So far no case of cholera has been imported into this country, and every week that the season advances tends to make us more secure. Cholera in Italy is also less dangerous to us than the prevalence of the disease in France. The week has, however, not been entirely free from rumours of mischief at home, and the account which Mr. Holder of Hull published in *The Times* as to the passage across the country, from Cardiff to Hull, of a sailor who, after arriving at Marseilles, was still suffering from somewhat copious diarrhœa, can hardly be passed over in silence. It is true that, as yet, the truth of the statement that he successfully evaded the system of medical inspection at Cardiff rests solely on the word of a man who apparently had only recently got over a fit of drunkenness; and the sanitary officials at Cardiff have the reputation of being thoroughly efficient. But there is always the possibility that the most vigilant may be deceived by fraudulent statements, and the story as told hitherto rather savours of some such device. We hope to learn the true circumstances of the case.

The *London Gazette* of August 22nd and 26th contains notifications to the following effect:—

All vessels from the Italian peninsula arriving at Greek ports will be subjected to eleven days' quarantine. On arrivals from the French coast of the Atlantic five days' quarantine will be imposed.

The Danish Government has ordered that the provisions of sec. ii. chap. i. of the law of July 2nd, 1880, be enforced against ships coming from any ports of the mainland of Italy on the Gulf of Genoa or the Sea of Tuscany.

At Malta, arrivals from Sicily and Sardinia are admitted to free pratique.

All vessels proceeding to Monte Video from Toulon, Marseilles, or other places where cholera is known to exist, have to undergo eight days' quarantine on arrival.

At Gibraltar, a quarantine of seven days is imposed on arrivals from Italy, and all vessels arriving from ports east of Suez are admitted to free pratique, provided they are furnished with clean bills of health and that the health of all on board is satisfactory.

The Norwegian Government have declared all the ports in Great Britain and Ireland, Belgium, and Holland, as well as the German ports in the North Sea, infected with cholera, no quarantine, however, being imposed upon vessels arriving from an infected port unless cases of cholera have actually occurred on the passage.

The Portuguese Government have issued a notice intimating that the port of Cette is declared infected with cholera morbus since the 1st inst.

The Governor of the West African Settlements reports that all vessels arriving from any infected place (Toulon and Marseilles, and all places in free communication with those ports) will be subjected to seventeen days' quarantine, to count from the date of leaving an infected port, or from the date of the recovery of the last case of sickness on board.

WILLS OF MEDICAL MEN.

THE Scotch Confirmation under seal of office of the Commissariot of the county of Edinburgh, of the trust disposition and settlement of Alexander Wood, M.D., late of 12, Strathearn-place, Edinburgh, who died on Feb. 26th last, granted to John James Graham Brown, M.D., the Rev. James Wood Brown, and Mr. Daniel Molloy Massey, the executors nominate, has now been sealed in London, the value of the personal estate in England and Scotland amounting to over £26,000.

The will of Henry Allen Aldred, M.D., late of 4, Westbourne-park, who died on May 21st last in Hyde-park, was proved on the 13th ult. by Mrs. Jane Fraser, the sister, the value of the personal estate exceeding £17,000. The testator leaves all his real and personal estate upon trust for his said sister for life, and then for her children as she shall appoint.

The will of Joseph John Alphonsus Brown, M.D., late of Grantham House, Grantham, Lincolnshire, who died on June 13th last, was proved on the 11th inst. by Mr. Richard Dunkling Beasley and Mr. George William Shipman, the value of the personal estate amounting to over £15,000. The testator, after giving all his medical books to his eldest son, Joseph L'Oste Brown, leaves the residue of his estate between all his children and Anne L'Oste Norris, the child of his deceased daughter, Josephine Anne Norris.

The will of George Harriss Strange, late of Wardrew House, Lyonsdown-road, New Barnet, Herts, and of 92, Hatton-garden, surgeon, who died on June 2nd last, was proved on the 4th ult. by Mrs. Emily Strange, the widow, Mr. Robert Fisher Young, and Mr. Samuel Durham Kember, the executors, the value of the personal estate exceeding £1200. The testator bequeaths £100 and all his household furniture and effects to his wife and complimentary legacies to his other executors. The residue of his real and personal

Digitized by Google

estate is to be held upon trust for his wife for life, and on her death or marriage again for his son George William Davies Strange.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Hanson Freeman, of Bilton Court, near Knaresborough, Yorkshire, £1000 each to the Halifax Infirmary and the Harrogate Bath Hospital.—Mrs. Jane Brown Grieve, of Orde House, Berwick-on-Tweed, £1000 to the Catholic Hospital of St. John and St. Joseph, Great Ormond-street, in affectionate remembrance of the late James Grieve.—Mrs. Mary Armitage, of 1, Redcliffe-square, the Boltons, Brompton, £200 each to Charing-cross Hospital, the Hospital for Diseases of the Hip in Childhood, Queen's-square, Bloomsbury, and the Convalescent Institution, Chatham, near Redcar, Yorkshire.—Mr. Joseph Nutter, of Park-terrace, Halifax, £1000 each to the Halifax Infirmary and the General Infirmary, Bradford; £500 to the Bradford Fever Hospital; and £100 each to the Blind Asylum and the Eye and Ear Infirmary, Bradford, and Ilkley Bath Hospital.—Mr. James Lyne Hancock, of Blenheim Lodge, Putney-heath, and of 266, Goswell-road, vulcanised india-rubber manufacturer, £1000 each to King's College Hospital and St. George's Hospital; and £500 each to St. Bartholomew's Hospital, the Hospital for Diseases of the Chest, City-road, the Royal Hospital for Incurables, Putney, and the London Hospital, Whitechapel.—Mrs. Catherine Abram, of Belsize-terrace, Hampstead, £1000 to the North London Consumption Hospital.—Miss Martha Butler, of 25, Marlborough-buildings, Bath, £200 to the Bath United Hospital.

EXAMINATION OF CANDIDATES FOR THE ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

THE following were the questions set at the recent competitive examination for Her Majesty's British Medical Service:—

Anatomy and Physiology (Monday, August 11th, 1884, from 10 A.M. to 1 P.M.)—1. Describe the tibia, giving an account of the origin and insertion of the muscles arising from or inserted into it. Describe also the structure of the knee-joint. 2. Describe the abdominal aorta, giving an account of its relation to neighbouring parts. Enumerate its branches and describe in detail the relation and distribution of those of the cœliac axis. What are the sources of animal heat, and the nature of the mechanism by which it is regulated and distributed? Explain how it is that a mean temperature of the body is preserved under exposure to the influence of either extreme heat or extreme cold. 4. Describe the origin, distribution, anatomical relations, and functions of the spinal accessory nerve and its branches. 5. Describe the dissection by which you would expose the parotid gland. Give an account of its connexion and relation to the various neighbouring structures.

Surgery (Monday, August 11th, 1884, from 2 P.M. to 5 P.M.)—1. What are the causes which give rise to extravasation of urine in the perineal region? Describe the appearance of the parts in the various stages of extravasation, and the treatment, and the consequences of such an injury. Describe the symptoms by which chronic inflammatory swelling of the testicle may be diagnosed from any other enlargement of that organ, and the treatment to be adopted for the relief of the first-mentioned condition. 3. Explain generally what is understood by the term "tertiary syphilis." What tissues does it most frequently affect, and what should be the treatment under its various conditions? 4. What are the constitutional and local causes and general characteristics of gangrene affecting any portion of the lower limb in old age, independent of any severe accident; and what should be the treatment, according to the various stages or conditions of the malady? 5. Describe the conditions known as "caries" of bone. What bones are most commonly thus affected, and what serious complications may follow when it attacks certain bones? What are the best local and constitutional measures to be recommended under these various circumstances? 6. Describe the appearance and conditions of a knee-joint when the seat of acute synovitis, the treatment of such a case, and any unfavourable symptoms that may ensue when the acute state has subsided.

Medicine (Tuesday, August 12th, 1884, from 10 A.M. to 1 P.M.)—1. Explain the meaning of vaccination. Describe its purpose as first applied to the human race; and mention how, when, and by whom it came to be so employed. Explain what is meant by primary vaccination, and what by secondary vaccination or revaccination; and describe the regular phenomena which follow each of these operations; also describe the appearance of a perfect vaccine pustule, and of the scar which is typical of a gen[illegible] and how its characteristic appearance is brought about. [illegible]er, the *rationale* of "arm to arm" vaccination, and [illegible]ge at which primary vaccination is to be done, and the [illegible] to secure its success. Lastly, explain how "sufficien[illegible]vaccination is to be judged of, and how [illegible]. What are the indications afforded by the [illegible] of its membranes, and the [illegible] [illegible] [illegible]

organised, that the building bye-laws should be strictly observed, that polluted wells should be closed, and that adequate means of isolation should be provided. There can be no question but that the work here indicated is necessary. We can only regret that, in view of the past history of the place, as shown by the want of action at Aveley, we cannot look very hopefully into the future sanitary history of the district.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hexham (Rural).—Dr. Maclagan's annual report for 1883 is prepared with much care, although the matters it contains are this year mainly of interest to the locality itself. An account is given of the long-continued attempts to provide Prudhoe with a proper water-supply, the almost endless correspondence between the authority, the Local Government Board, and the Newcastle and Gateshead Water Company having so far led to little more than delay. A detailed account is given of the sanitary circumstances with which the several cases of infectious disease have been associated, and the occasion of their occurring is utilised for the purposes of getting sanitary work carried out. In a population of 34,086, the death-rate was 15·9 per 1000. A considerable increase took place in the deaths from the several so-called zymotic diseases; but the infantile mortality, a matter to which much attention had been devoted, underwent diminution, and fortunately the number of deaths uncertified by any medical practitioner has also been reduced.

Holme Valley (Urban).—The population of this district being estimated at 21,341, the birth-rate was 32·1 and the death-rate 19·0 per 1000. At Honley an outbreak of enteric fever took place, the number of attacks being 23 and the deaths 6. The cause was obscure; but it was probably due to defective drainage, and it is satisfactory to learn that in consequence a complete system of public drainage is now being carried out, and that Dr. Scougal has pressed upon the sanitary authority the importance of compelling all householders to connect their houses with the system. Although it is evident from the description of sanitary work which is given that disconnexion and like improved structural alterations are carried out in the district, yet it does not appear whether or no bye-laws are in force for Honley which will ensure that the new house-drain connexions shall be made after the manner illustrated in the Annotated Model Bye-laws. If not, the needed code of bye-laws should at once be adopted, otherwise it will be difficult to secure such works of house drainage as shall be free from danger to health.

Peterborough (Urban).—The death-rate for this city was 20·1 per 1000 in 1883. It is painful to read, year after year, of illness associated with the use of contaminated wells in an ancient town like Peterborough. Indeed, it is impossible to understand how the soil on which Peterborough stands can be regarded by anyone as affording a source of water-supply which can possibly be free from the risk of contamination. Dr. Paley has, however, again to refer to the subject, and shows clearly how unwise it is to trust to the mere chemical ingredients of a single sample of water when the question of its possible pollution is under consideration. The outbreak of typhoid fever and diarrhœa in one locality, which should have been replaced by proper closets, and the water, long suspected, was let alone because it was never found to contain organic matter in more than a very small quantity. Unfortunately, a very infinitesimal quantity of one kind of organic matter may be more potent for mischief than a large quantity of some other organic contamination. Another recurrence of illness in the same locality fresh investigation led to the discovery that the well was polluted owing to a blocked drain. Here, as elsewhere, a careful examination of the surroundings of a well gave a more valuable information as to its possible pollution than mere chemical examination.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 23rd inst., 5864 births and [illegible] were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the two preceding weeks had been 21·9 and 24·1 per 1000, further rose last week to 25·6. During the first seven weeks of the current quarter the death-rate in these towns averaged 22·2 per 1000, against 20·4 and 20·1 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 17·4 in Bristol, 17·9 in Derby, and 20·5 in London. The rates in the other towns ranged upwards to 35·9 in Bolton, 36·9 in Cardiff, 37·3 in Leicester, and 39·3 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which in the two preceding weeks had been 911 and 1106, further rose last week to 1314; these included 995 from diarrhœa, 77 from whooping-cough, 71 from measles, 67 from scarlet fever, 53 from "fever" (principally enteric), 27 from small-pox, and 24 from diphtheria. These diseases caused the lowest death-rates in Plymouth and Bristol, and the highest in Sheffield, Preston, and Norwich. The highest death-rates from diarrhœa were recorded in Hull, Preston, and Norwich; from measles in Bolton and Halifax; from scarlet fever in Sheffield and Cardiff; from whooping-cough in Huddersfield and Halifax; and from "fever" in Cardiff and Bolton. The 24 deaths from diphtheria in the twenty-eight towns included 17 in London. Small-pox caused 21 deaths in London (exclusive of 2 metropolitan cases registered outside Registration London), 3 in Sunderland, 1 in Liverpool, 1 in Sheffield, and 1 in Birkenhead. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the six preceding weeks from 1368 to 640, further fell to 587 on Saturday last; the cases admitted were 53, against 110 and 64 in the two previous weeks. The Highgate Small-pox Hospital contained 28 patients on Saturday last, 5 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined from 198 to 162 in the three preceding weeks, further fell to 157, and were slightly below the average. The causes of 108, or 2·5 per cent., of the 4293 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Norwich, Leicester, Nottingham, and in four smaller towns. The largest proportions of uncertified deaths were recorded in Sunderland, Oldham, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·7 per 1000 in each of the two preceding weeks, rose to 21·8 in the week ending the 23rd inst.; it was 3·8 per 1000 below the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 13·4 and 14·5 in Perth and Edinburgh, to 26·5 in Glasgow and 29·4 in Paisley. The 524 deaths in the eight towns included 74 which were referred to diarrhœal diseases, 28 to whooping-cough, 14 to scarlet fever, 13 to diphtheria, 6 to measles, 6 to "fever," and not one to small-pox; in all, 141 deaths resulted from these principal zymotic diseases, against 114 and 109 in the two preceding weeks. These 141 deaths were equal to an annual rate of 5·8 per 1000, which was 2·0 below the average rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 51 in each of the two previous weeks, rose to 74, and considerably exceeded the number in the corresponding week of last year; 45 occurred in Glasgow, 8 in Dundee, and 6 in Paisley. The 28 deaths from whooping-cough were within 1 of the number in the preceding week, and included 13 in Glasgow and 5 in Aberdeen. The 14 fatal cases of scarlet fever were all returned in Glasgow. The 13 deaths from diphtheria showed a considerable increase upon recent weekly numbers; 5 occurred in Glasgow, 3 in Aberdeen, 2 in Dundee, and 2 in Paisley. The 6 fatal cases of "fever" corresponded with the number in the preceding week, and 5 of the 6 deaths from measles were recorded in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns, which had declined in the four preceding weeks from 89 to 64, further fell to 58, and were 9 below the number returned in the corresponding week of last year. The causes of 72, or nearly 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 22·4 and 24·2 per 1000 in the two preceding weeks, further rose to 30·3 in the week ending the 23rd inst. During the first

Digitized by Google

eight weeks of the current quarter the death-rate in the city averaged 23·1 per 1000, the rate during the same period being equal to 22·7 in London and 16·7 in Edinburgh. The 204 deaths in Dublin last week exceeded by 41 the number in the previous week, and included 45 which were referred to the principal zymotic diseases, against numbers increasing from 16 to 33 in the four preceding weeks; of these, 25 resulted from diarrhœal diseases, 13 from scarlet fever, 3 from whooping-cough, 3 from "fever," 1 from diphtheria, and not one from measles or small-pox. These 45 deaths were equal to an annual rate of 6·7 per 1000, the rate from the same diseases being 4·7 in London and 2·5 in Edinburgh. The 25 fatal cases of diarrhœa showed an increase of 3 upon the number in the previous week. The deaths from scarlet fever showed a considerable increase upon recent weekly numbers, and were higher than in any preceding week of the year. The fatal cases of "fever" showed a further decline from those returned in the two previous weeks. Five inquest cases and 3 deaths from violence were registered in the city during last week, and 51 deaths occurred in public institutions. The deaths both of infants and of elderly persons showed an increase upon recent weekly numbers. The causes of 30, or nearly 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIAN MEDICAL SERVICE.

WE learn from the *Indian Medical Gazette* that junior medical officers of the Indian Medical Service having been made available, under certain conditions, for duty with British troops, are to receive, when marching with British troops from one station to another, charge allowances on a scale equivalent to what is at present sanctioned for the temporary charge of native troops—viz., for an entire regiment 100 rupees a month, for a wing of a regiment or detachment of numerical strength equal to a wing 75 rupees, for a battery of Royal Artillery 50 rupees.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Hugh Mackay Macbeth to be Brigade-Surgeon, vice R. C. Lofthouse, M.D., granted retired pay; Surgeon-Major William West Quinton, M.B., is granted retired pay, with the honorary rank of Brigade-Surgeon.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon William H. Putsey, to the *Boscawen*, for service in sick quarters at Portland; Staff Surgeon William J. Rankin, M.D., to the *Boscawen*; Staff Surgeon Robert W. Biddulph, M.B., to the *Duncan*, additional; Surgeon Alfred H. Kelly, M.D., to the *Valiant*; Surgeon James A. Collot, to the Royal Marine Artillery Division at Portsmouth; and John Paulin to be Surgeon and Agent at Peel, Isle of Man; Surgeons William W. Jacobs, Alexander F. Harper, Herbert W. A. Burke, and Edward R. D. Fasken, to the *Royal Adelaide*; Surgeon Evan St. M. Nepean, to the *Pembroke*; Surgeon Arthur S. Nance, to the *Indus*; Surgeon Alexander G. Andrews, to the *Asia*; Surgeon James C. F. Whicher, to the *Impregnable*; Surgeons Edward W. von Tunzelmann, M.B., Edward B. Townsend, Alexander G. Wildey, Patrick B. Handyside, M.B., Harold R. Osborne, James M. Rogers, Charworth L. Nolan, M.B., Harold F. D. Stephens, Francis H. Julyan, Edward C. Ward, M.B., William R. Minching Young, George L. Baker, Herbert W. G. Doyne, Alexander B. Murdoch, M.B., Thomas Dunlop, M.B., Samuel Johnson, M.B., George A. Dreaper, and William H. O'Meara, to the *Duke of Wellington*.

ARTILLERY VOLUNTEERS.—1st Lanarkshire: Surgeon Robert Watson, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.—1st East Riding of Yorkshire: Surgeon Archd. Megget resigns his commission.

ENGINEER VOLUNTEERS.—2nd Tower Hamlets (East London): The services of Acting Surgeon Reginald Archfield Fergusson, M.D., are dispensed with.

RIFLE VOLUNTEERS.—1st Cornwall (Duke of Cornwall's): Acting Surgeon James Blamey resigns his appointment.—20th Middlesex (Artists'): Walter Pearce, Gent., to be Acting Surgeon.—3rd Monmouthshire: Acting Surgeon Octavius Edward Bulwer Marsh resigns his appointment.—5th Lanarkshire (Glasgow 2nd Northern): Ernest Kingscote, Gent., M.B., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

"REARING OF HAND-FED INFANTS."

To the Editor of THE LANCET.

SIR,—I fear, good as the substitute advised by Mr. Walker in your last issue may be for the artificial rearing of infants, he will find but few who would take the trouble, even if his, or rather Dr. Frankland's, method were commonly known of compounding the daily supply; it is too complicated for the purpose, and the knowledge how to make it can never be sufficiently promulgated among mothers and nurses to bring it into general use; and I must say here I think the advice of Dr. Owen is excellent, as his system is within the reach of the most indolent and the most ignorant.

In my letter in THE LANCET of Aug. 9th, I think I pointed out more likely reasons why artificial feeding is so disastrous to infant life, and I believe that if those who have the care of dry-nursed children could be induced to feed them for the first few months of existence on new cow's milk diluted with an equal, or rather more than an equal, part of water, and sweetened with sugar of milk instead of common sugar—which induces lactic fermentation, and therefore increases the tendency to infantile diarrhœa—we should not hear so much of the awful mortality of young infants. I have never found this turn curdy, or disagree where I have recommended it, because when any complaint has been made to me of the infant rejecting it, and before permanent mischief was done, I have advised the addition of a little lime-water, and a slight curtailment of the supply. We all know that cow's milk is acid in reaction and human milk is alkaline, and knowing this it is always advisable to tell the nurse or mother how to correct this state of affairs. Under any system of artificial feeding an infant takes in a much larger quantity of food than when it is suckled; but it is not digested, and herein lies the cause, combined with irregular feeding and dirty bottles, of the mischief. It must not be supposed for one moment that I advocate the cow as the proper mother of an infant. I think the present system of rearing dry-nursed children the curse of this generation, and posterity will have to pay a bitter price for the indolence—if nothing worse—of the mothers of the present day, who, obeying the dictates of fashion, delegate to the nurse the duty that nature assigned to themselves. "Can a woman forget her sucking babe?" asks the prophet. Alas, the answer is not far to seek, and the infant mortality of the present day supplies a melancholy answer. Fancy this advice of Chavasse, advice followed by thousands of mothers; here is pandering to laziness with a vengeance: "A good plan is for the nursemaid to have a half-pint bottle of new milk—which has been previously boiled—in the bed, so as to give a little of it instead of the breast. The warmth of the bed will keep the milk at the proper temperature, and supersede the use of lamps, candlesticks, and other troublesome conveniences." Of course it will, and also cause it to turn and decompose in a few hours. No; our duty as medical advisers is to teach mothers that dry nursing is only another name for either killing their offspring or being blessed, or rather cursed, with weakly, rickety, puling children, that develop as they grow older, if they live long enough, tubercular disease and the other ills that follow in the train of early malnutrition. Must we go to the ancients for lessons? Mahomed, in the Koran, commands mothers to suckle their children for *two* years. "Mothers," he says, "after they are divorced, shall give suck unto their children full two years to him who desireth the time of giving suck to be completed." (Koran, chap. ii.) Dion relates that the nurse of Caligula anointed her nipples with blood before she gave him suck, which accounted for his cruelty, as he did not inherit it from his father or mother. Giraldus was of opinion that men and beasts participate in the nature and conditions of the animal whose milk they were brought up on, and he cites the case of a pig that suckled a brach, and when she was grown "would miraculously hunt all manner of deer and that as well, or rather better, than any ordinary hound." Who was that Queen of France, I wonder, of whom it is said that so careful was she that her child

Digitized by Google

should be suckled by herself alone, that when in her absence a strange nurse had done so, she was never quiet till she had made the infant vomit it up? What an example to the present race of mothers. Cato, it is said, would make his servants' children suck upon his wife's breast because by that means they would love him and his the better. If there is anything in these opinions of the ancients, and the children imbibe with the mother's milk a greater love for the parent, it may be an inducement to many mothers, if it were known, to suckle their own offspring; and if feeding, as is done in the present day and has been done for the last twenty years to many of the rising generation, on cow's milk gives to the infant the attributes of its foster mother, we need not go very far to seek for the origin of the "masher," though we may deplore the fact that so many calves have been robbed of their due quantum of nourishment to aid in bringing him to his present state of perfection.

I am, Sir, yours truly,

NATHANIEL EDWARD DAVIES.

Sherborne, August 24th, 1884.

THE ANCOATS MURDER: CASE OF J. J. DONNELLY.

To the Editor of THE LANCET.

SIR,—I have read Dr. Hughes Bennett's letter in your issue of to-day with interest, yet also with surprise and regret. Dr. Bennett is to be admired for his warm sympathy with the unfortunate, but there is something else required: a true man is just as well as generous. As was so well said in your article of the 9th inst. on the above subject—"Science knows nothing of sentiment, and we cannot afford to strain points for the sake of humanity." How can we expect judges, juries, or the public to treat us with respect if we allow our feelings or prejudices to warp our judgment—if, instead of giving evidence or expressing opinions in strict accordance with facts, we act as partisans? Is there anything more humiliating than to see or to read of medical men in a court of justice ranging themselves on opposite sides? It is the duty of a medical witness to speak the truth, the whole truth, and nothing but the truth; he has nothing to do with the consequences—those must be left to the judge and jury.

Dr. Bennett intimates that if he had been called as a witness in Donnelly's case, "he could have strongly advocated his irresponsibility." We are further told that "no one acquainted with the mental condition of the prisoner, and reading the public reports of his trial, could have the slightest doubts of his irresponsibility in the crime he committed." Dr. Bennett is dominated by the notion that Donnelly, on the night when he committed the crime for which he was sentenced to be hung, was suffering from epileptic furor. But there is no evidence to support such a view—at least, I cannot find any in the published reports. The deputy coroner, who is a barrister, went very carefully into this matter; he elicited from the prisoner's father that he had not had a fit that night; neither had he the premonitions or accompaniments or consequents of a fit. The father, after more than twenty years' experience, would know well the symptoms indicating a seizure. Both father and brother described these, but, with the exception of turbulence, Donnelly showed no signs of an attack; the family knew too well the true cause of his misbehaviour. Donnelly, unfortunately, was addicted to drink.

A consideration of the whole of the facts will, I think, show that Donnelly, from the time he came home at half-past nine on Sunday night up to that of his capture, knew not only what he was doing, but the probable consequences of his acts. After the father took up the poker and threatened to strike the young man with it, the latter checked his turbulence; and when finding himself locked out, it burst forth again. Instead of venting his anger on his father, who he knew had shut him out, he rushed to his own room out of his father's way. When subsequently his father somewhat cruelly refused him water, he again repressed any manifestation of rage. After having committed the murderous assault on two defenceless women, he precipitately made his escape and tried to conceal himself. Now, an epileptic suffering from maniacal excitement is as devoid of craft as he is blind to danger. Opposition renders him furious and reckless; neither poker nor pistol has any terrors. It is true that Donnelly attacked his sister in a paroxysm of anger, but it is certain that if his father had been in the room armed with the poker he would again have restrained his rage. Had Donnelly's father had any reason to believe that his son was threatened with a fit, instead of thwarting him he would have tried to calm and soothe the young man; but the family knew well that what Donnelly was suffering from was the effect of drink.

In summing up, the deputy coroner told the jury that "there was no evidence that the man was out of his mind at the time he committed the act, and if he was the worse for drink, that was no excuse, but rather an aggravation." The jury which tried Donnelly at the Assizes, having all the facts before them, came to the conclusion that Donnelly was sane when he committed the murder, and therefore found him guilty. The law blunderingly fails to discriminate between a deliberate cold-blooded murder and one committed in a sudden outburst of anger; it barbarously decrees death in both cases. The jury which tried Donnelly marked their sense of the difference, and therefore recommended him to mercy; but, so far from having deserved censure, the jury deserve the utmost credit for having discharged an onerous and very painful duty in a thoroughly conscientious and intelligent manner.

I am, Sir, yours truly,

Manchester, Aug. 16th, 1884. R. MARTIN.

"OUR MONSTER COUNTY LUNATIC ASYLUMS."

To the Editor of THE LANCET.

SIR,—Your article on the above, in the issue of August 23rd, is well-timed, and cannot fail to draw attention to the subject. It is now pretty generally recognised that asylums containing more than 800 patients are difficult of management, if not unwieldy and less economical than smaller institutions. You, however, allude to cases in which "from 1500 to 2000 insane individuals, *supposed to be patients*, are under the care and control of one medical man." Surely you should have added "aided by one, two, or more assistant medical officers." Otherwise the statement is misleading. In these days of scientific advancement, and the development of the healing art, the word "asylum" ought to be almost an anachronism. Patients struck down with mental disease should without delay be placed under the most skilled treatment possible in "hospitals for the insane," institutions in which the main object is to combat the disease in its earliest stage, and to restore the individual to the community with *mens sana in corpore sano*. Such hospitals would require a highly qualified medical staff with clinical assistants and all the necessary means of treatment, and should not contain more than from 100 to 150 beds. Cases after a fixed time deemed incurable should be transferred to the "asylums," the "homes for incurables requiring no special medical treatment." The "hospital for the insane" would be costly at the outset, but in the end would prove the more economical, the more humane, and the more creditable to civilisation. Heretofore the lunacy laws have been framed on the score of humanity solely. Surely the day is not far distant when the advancement of psychological science and the increased facilities for cure will demand consideration at the hands of our legislators. At the present time the medical staff of the county asylums do their utmost for the treatment with view to cure of the patients under their charge, but, from the ever-increasing numbers of the insane, "an enormous mass of material annually passes under their eyes which is almost wholly unutilised." Moreover, the four shillings per week Government capitation grant for the insane poor has of late years flooded the pauper asylum with idiots, imbeciles, and aged dements, because their transfer rids the unions of troublesome cases which, with this pecuniary aid, can be maintained as cheaply, if not more economically, in the county asylums.

I am, Sir, your obedient servant,

ERNEST W. WHITE, M.B. Lond., &c.

Kent Lunatic Asylum, Chartham, August 23rd, 1884.

*** Our statement relative to the number of patients under one medical man is in no way invalidated by the presence of assistant medical officers. The treatment of every patient in an asylum devolves virtually upon the Superintendent, and upon him alone the responsibility in the matter rests.—ED. L.

NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

THE ROYAL VISIT.

THE Royal week and visit have come to an end, and from what I hear and see on all sides I think we may fairly say they began and ended well. The general arrangements were complete and satisfactory, while the order maintained by the vast concourse during the visit, occupying several days, was remarkable indeed. The police report states that there were fewer cases of intemperance and disorderly conduct than during an ordinary week. The Mayor has scored a great success, and he deserves the special thanks of his fellow citizens, as he has already received those of Royalty. Where all have worked so well, it is no harm to mention the special and useful services of the Ambulance Corps rendered on the day of the procession. Owing to the extreme heat prevailing and the pressure of the crowd, as many as eight or nine people dropped down exhausted at one of our street corners. They were immediately attended to and removed to the tents of the corps, and not allowed to depart until fully restored. As might be expected, during the following days a very large number of minor accidents were admitted into the infirmary, and were duly attended to, but there was a remarkable absence of anything serious.

NEWCASTLE INFIRMARY.

At the last quarterly meeting the House Committee was charged with the nomination of a special committee for the consideration of the pressing need for a larger infirmary, and of the ways and means by which either the present building can be enlarged or a new one erected. Our *Daily Chronicle* points out, in reference to the above resolution, that the site of the building, although a good one in 1750, is not a desirable one now; and that while during the last quarter of a century the augmentation of the city and surrounding district, as regards population, has been enormous, the increased accommodation provided since the opening of the new wing in 1854 has been very small; that the great changes which recent years have developed in our social system render it very desirable that the old plan of admission by subscribers' tickets should be abolished; and that the institution should be converted into a free hospital. The *Chronicle* also points out that, although the present building possesses two undeniable advantages—namely, its central position and its open frontage to the south,—its drawbacks are serious, and more than counterbalance these benefits. A line of railway, on which busy traffic is conducted day and night, runs along the whole length of the main front, and two sides of the building are surrounded by the cattle and sheep markets of the city. The noise and bustle arising from their contiguity are seriously detrimental to the purposes of the infirmary. It was further pointed out at the meeting that, although the house has accommodation for 200 beds, there has often been 230 in use; and that in times of pressure female patients have to be sent to the lock ward—a procedure, to say the least of it, very undesirable.

SANITARY DEFECTS AT ALNWICK.

A recent coroner's inquest on a case of English cholera at Alnwick has brought to light what is described as "a scandalous state of affairs" as regards sanitary matters in the ducal town. From the evidence of Mr. J. H. Davidson, it would appear that there is no registration of lodging-houses in the town, and that he has frequently drawn the attention of the Local Board to these defects, yet no action has been taken. Mr. Davidson has seen as many as twenty people crowded into two small rooms in a very filthy condition. The verdict of the jury was in accordance with the evidence—namely, "Death from English cholera." The coroner, in opening the inquiry, stated he considered it to be his duty as much to inquire into the death of a person from preventable causes as from accident.

Newcastle-on-Tyne, August 26th, 1884.

AMERICAN EXHIBITION.—An exhibition of the arts, manufactures, products and resources of the United States of America will be opened in London on May 1st, 1886.

IRELAND.

(From our own Correspondent.)

CASES OF ALLEGED CHOLERA IN KILMACTHOMAS WORKHOUSE.

A MAN named Kennedy, a native of Glasgow, who had stowed himself on board a Liverpool vessel, and was landed at Kinsale, was admitted on the 20th inst. to Kilmacthomas Workhouse. On the following morning he complained of being attacked with vomiting and purging, and a couple of hours afterwards was seen by Dr. Walsh, medical officer of the union. Dr. Martin of Portlaw also saw the patient, and he and Dr. Wynne considered it an undoubted case of Asiatic cholera. Kennedy became worse, and died at nine o'clock the same evening. Dr. Walsh is doubtful of the case, and he considers it an open question whether the disease was Asiatic or English cholera. The Local Government Board having been communicated with, sent down Dr. Brodie to inquire into the matter, but so far the result has not been made known. I may add that since Kennedy's death a female of weak mind, resident in the workhouse, presented choleraic symptoms and died on the following day. So far all sanitary precautions have been taken by Dr. Walsh; the patient's clothes have been burned, as well as the clothes worn by the male nurse and attendants, and the casual ward and room in the Fever Hospital have been disinfected and closed.

THE ROYAL UNIVERSITY.

Plans for altering the University buildings and for adding a new wing have been approved, and will be commenced immediately, at an estimated cost of £25,000. A chemical laboratory 120 ft. by 30 ft. will form a portion of the wing, and adjoining this will be smaller laboratories, and an apartment for the study of histology 58 ft. by 16 ft. The physical laboratory will be 90 ft. by 30 ft., and close to this will be the physiological museum, 57 ft. by 20 ft. Behind these apartments will be the dissecting room, 120 ft. by 30 ft., and in connexion with it a smoking room for students, lavatories, and retiring rooms. At the centre of the building there will be placed a tower, at an elevation of 90 ft., which will be utilised as a ventilating shaft, in connexion with which the different apartments will communicate. The works will probably occupy two years.

THE DUBLIN HOSPITALS.

From the twenty-sixth report of the Board of Superintendence of the Dublin Hospitals which receive grants from Parliament, it appears that there are nine of these institutions, two being lying-in, two ophthalmic, two fever, one lock, and three general hospitals. On the 1st April, 1883, there remained 815 patients in these hospitals, while the number admitted during the year was 9560, making a total under treatment of 10,375, of whom 9226 were discharged cured or relieved. The deaths amounted to 433, or a mortality of 4·69 per cent. on the cases treated to a termination. The average annual cost per bed for maintanance and for establishment charges ranged from £26 18*s.* 2*d.* in the Hospital for Incurables, to £72 4*s.* in Cork-street Fever Hospital, and £85 14*s.* 6*d.* in the Coombe Lying-in Hospital.

The post of lecturer in Operative Surgery in the Medical School of Trinity College, which has been resigned by Mr. Butcher, will not, it is stated, be filled up.

A good many children in the North Dublin Union have recently been suffering from ophthalmia, which, owing to overcrowding, assumed the proportions of an epidemic. The medical officer has recommended that these cases should be sent to the new buildings at Cabra.

The Local Government Board have threatened to dissolve the Midleton Board of Guardians should they persist in neglecting to procure a proper water-supply for the inhabitants.

Dublin, August 26th, 1884.

BELFAST.

(From our own Correspondent.)

QUEEN'S COLLEGE.

FROM the report of the President of Queen's College, Belfast, for the session 1883-4, which has just been issued, I gather that the total number of students enrolled during

Digitized by Google

the year in each faculty was as follows:—Arts, 205; Law, 22; Engineering, 8; Medicine, 264. Of these, 18 attended in more than one faculty, so that the entire number of students upon the books was 481, of whom 456 matriculated. As compared with the previous year, there was an increase of 13 in Arts, a decrease of 7 in Law, 4 in Engineering, and 21 in Medicine. The total aggregate decrease was 21. The main cause of the decrease was, the President thinks, the dissolution of the Queen's University in the session of 1881–82. He states that up to that time the annual increase in the number of students had been steady and rapid, while at this date it ceased, and a serious decrease at once began, amounting in the session 1882–83 to 65. While the President shows the baneful effect the destruction of the Queen's University had upon the College as a whole, he points out that the Medical School has suffered most. The Royal University, which took the place of the Queen's, at once made a change in the medical curriculum. Candidates for medical degrees are by it compelled to pass the first university examination in Arts before being permitted to present themselves for the first professional examination. Large numbers of the students, the President says, who under other circumstances would prefer to study in Belfast and to take degrees in the Royal University, now go to the Scotch Universities and to the examining boards where no such rule exists. He thinks that the study of an Arts course should not be enforced, but should be optional. The taking of a degree in Arts should likewise be left to the choice of the student.

PROFESSOR REDFERN, M.D.

I am very glad to be able to announce that arrangements have been made by which the distinguished Professor of Anatomy and Physiology will continue to lecture at Queen's College. His resignation at the present juncture would have been a great loss to the medical school in which he has been so long a conspicuous figure. His brilliant address at the late meeting of the British Medical Association will long be remembered by those present during its delivery.

THE ROYAL HOSPITAL.

The quarterly meeting of the General Committee was held on Monday last. From the report I learn that Lord Ashley has become President of the hospital in the place of the late Marquis of Donegal. Reference was made to the refurnishing of one of the wards by Miss Duffin, and to the fact that the Board, by the decision of the Master of the Rolls, may use a portion of the Convalescent Home for the treatment of consumptive patients. In this way they will be able to utilise, for the treatment of consumptive cases, the gift of Mr. Forster Green of £5000. The unpleasant feature in the report is the fact that the balance against the hospital at the end of July amounted to £2295. To meet this there is to be a bazaar and fancy fair in the Ulster Hall next November. Dr. J. W. T. Smith was re-elected physician in accordance with the rule that members of the staff are elected for terms of four years, but are eligible for re-election. Dr. Smith is the senior physician. For the post of surgeon, vacant through the resignation of Dr. John Moore, there were two candidates—viz., Dr. T. K. Wheeler, who has been assistant-surgeon for two years, and Dr. Sinclair, the demonstrator of anatomy at Queen's College; the former gentleman was elected by a very large majority.

HOSPITAL SATURDAY.

On Saturday next this new scheme will be inaugurated, when an appeal will be made to all classes of the community at the corners of streets and in public thoroughfares, where ladies and gentlemen will gladly receive any contributions.

PARIS.

(From our Paris Correspondent.)

THE CHOLERA EPIDEMIC.

The cholera continues to reign in the South of France, but the epidemic is as yet localised in the departments of the littoral of the Mediterranean. The mortality fluctuates between three and eight daily at Toulon and Marseilles, but there has been a slight recrudescence during the past week, which has been attributed to the influx of the fugitives, and to the continued insanitary condition of these places. Panic has again set in among the inhabitants, which is extending to the other parts, and has caused a considerable decrease in the number of persons returning to their homes. At Toulon the unhealthy condition of the troops has been somewhat aggravated, and it is, in consequence, proposed to disperse them. The ambulances, which were about to be closed, have received orders to be kept open. Two medical men have succumbed to cholera — Dr. Maurice Cathala at Cette, and Dr. Eugene Fanton at Arles. Intelligence has also been received of the death at Aix of a Sister of Charity (Sœur Catherine), who has fallen a victim to the disease in the execution of her duty among the sick.

ENTERTAINMENT IN HONOUR OF M. CHEVREUL.

A rather interesting demonstration in the form of a public entertainment is being prepared, to be held in the Quartier Latin on the 1st September, to celebrate the birthday of M. Chevreul, the illustrious chemist and academician, who then enters upon his ninety-ninth year. He was born at Angers on the 31st of August, 1786.

AN EXHIBITION OF BABIES.

An exhibition of infants is to be held in Paris on the 30th of October next, and during as many days after as may be necessary. The infants are to be divided into four classes: 1st, from 1 year to 18 months old; 2nd, from 18 months to 2 years; 3rd, from 2 years to 30 months; 4th, from 30 months to 3 years. The jury will be composed of medical men and artists. The children who win the prizes will not be those of the fattest, but those of the best physical conformation as regards development of bone and muscle. There have been already upwards of 2000 applications, and the register will be closed on the 15th of September.

ERRATUM.—Near the end of my letter in your impression of last week, for "Grousi" read *Proust*.

Paris, August 27th.

Obituary.

DR. JULIUS COHNHEIM.

THE closing days of the Copenhagen Congress were saddened by the news announced in the section of Pathology by Professor Virchow of the death of one of the foremost of pathological investigators, Professor Julius Cohnheim of Leipsic. The event took place on the 14th inst., from the chronic affection (renal disease) from which he had been so long a sufferer. At the Congress a vote of condolence was at once passed to the widow of the eminent man; but no one cared then to attempt to review the labour of his too short life. His name stands at the head of the long list of illustrious pupils of an illustrious teacher; and from the time when he held the office of pathological assistant at Berlin to within a few months of his death he had been at work upon the problems of pathological phenomena. Although it is too soon to do justice to all the labours of his life, or to consider in what respects his work has advanced our knowledge, we cannot but feel that in his death science has sustained an irreparable loss. It is some consolation to know that in his "Vorlesungen" he has left behind an enduring monument of his work, which combines the results of physiology and pathology to an extent never before attained. Much of Cohnheim's teaching may be open to criticism as being speculative and transcendental, and yet he seldom advanced a theory without having it supported by well-attested facts. He combined in himself the qualities of the thinker and practical experimenter, and there can be no question that pathology has advanced considerably under his guidance. Julius Cohnheim was still in the prime of life, having just completed his ninth lustrum. After having studied medicine from 1856 to 1860 at Berlin, Würzburg, Greifswald, and Prague, he commenced practice at Berlin. In 1864 he served under Rudolf Virchow as assistant in the Pathological Institute in Berlin. In 1868 he was professor of the same department in the medical school of Kiel, and four years later he was transferred to the chair of Pathology in the University of Breslau, where his prælections attracted so much attention that on the first vacancy he was called to fill the professorship at Leipsic which became immediately associated with his best work. His name will live chiefly for his signal contributions to the doctrine of inflammation, his experimental proofs—by vivisection mainly—having been universally admired for their careful exclusion of every source of fallacy. In all inflammatory processes, without exception, such is his

Digitized by Google

demonstration, the greatest part of the pus-corpuscles consist of white blood-corpuscles that have passed through the walls of the veins and capillaries. Till this induction was arrived at, Virchow's view was the prevalent one—namely, that the pus-corpuscles are connective-tissue corpuscles transformed through cell-cleavage (*durch Zellentheilung umgebildete Bindegewebskörperchen*). Medicine, indeed, has formulated few more pregnant truths than that which Cohnheim put on a scientific basis:—"Without bloodvessels no inflammation is possible." An anticipation of this doctrine was made in 1848 by our countryman Waller, who occupies towards Cohnheim much the same position that Pacini does to Koch in the discovery of the cholera bacillus. In both cases the honour of converting partial into complete induction rests with the German pathologist.

GEORGE DOWNS, M.D.

DR. DOWNS, of St. Petersgate, Stockport, who died after a brief illness on the 17th inst., was born in 1807. At an early age he was apprenticed with Drs. Killer and Flint, of Stockport, where he remained until he proceeded to the Richmond School of Medicine and to Dublin for a course of study. In the year 1830 he took the degree of M.R.C.S., and fourteen years later the F.R.C.S. Eng., the M.D. of St. Andrews being conferred upon him in 1860. Throughout the whole of his career Dr. Downs has been a zealous and enthusiastic supporter of the Stockport Infirmary, and by his death that institution has suffered a great loss. In 1836 he was appointed honorary surgeon to this institution; in 1858 he resigned that position and was put upon the consulting staff; and at the time of his death he was senior consulting surgeon.

In 1866 Dr. Downs was added to the borough bench of magistrates. For many years he had acted as the certifying surgeon for the district under the Factories and Workshops Act. He was appointed to that position immediately on the passing of the statute and was understood to be the oldest living certifying surgeon in the country.

Medical News.

UNIVERSITY OF LONDON.—At the recent Intermediate Examination in Medicine the following candidates passed in Honours in the subjects mentioned:—

ANATOMY.

FIRST CLASS.

Thompson, J. E. (Exhibition and Gold Medal), Owens College.
Bradford, John Rose, B.Sc. (Gold Medal), University College.
Spencer, Walter George, St. Bartholomew's Hospital.
Clarke, James Jackson, St. Mary's Hospital.
Lys, Henry Grabham, London Hospital.
Wheatley, James, King's College.

SECOND CLASS.

Bowman, Henry Claxton, Owens College.
Clarke, William Frederick, Guy's Hospital.

THIRD CLASS.

Alexander Sidney Robert, Guy's Hospital.
Helme, Thomas A., University of Edinburgh and University College.
Brook, William Henry Breffit, St. Bartholomew's Hospital.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

FIRST CLASS.

Helme, Thomas A. (Exhibition and Gold Medal, University of Edinburgh and University College).
*Spencer, Walter George, St. Bartholomew's Hospital.
*Smith, John Anderson, St. Bartholomew's Hospital.
Bahadhurji, Kaikhosro Nasarvanji, University College.
Eq. Brook, William Henry Breffit, St. Bartholomew's Hospital. / Lyndon, Arnold, St. Bartholomew's Hospital. / Young, Charles Wheeler Forrest, St. Bartholomew's Hospital.
Eq. Burghard, Frédéric François, Guy's Hospital. / Permewan, William, University College. / Sunder, Charles Edward, University College.
Eq. Brown, Frederick Nathaniel, St. Bartholomew's Hospital. / Gardner, William Thomas, St. Bartholomew's Hospital. / Toogood, Frederick Sherman, University College.

SECOND CLASS.

Smith, Hugh, Guy's and London Hospitals.
Trevelyan, Edmond Fauriel, St. Bartholomew's Hospital.

THIRD CLASS.

Luff, Arthur Pearson, B.Sc., St. Mary's Hospital.
Eq. Featherstone, William Barltrop, Queen's and Mason Colleges, Birmingham. / Hamel, Julius, University College. / Holder, Sydney Ernest, University College. / Macevoy, Henry John, B.Sc., St. Thomas's Hospital. / Nevins, John Ernest, Guy's Hospital and Liverpool School of Medicine.

ORGANIC CHEMISTRY.

FIRST CLASS.

Young, Charles Wheeler Forrest (Exhibition and Gold Medal), St. Bartholomew's Hospital.
†Luff, Arthur Pearson, St. Mary's Hospital.
Burghard, Frédéric François, Guy's Hospital.

SECOND CLASS.

Bradford, John Rose, University College.
Macevoy, Henry John, St. Thomas's Hospital.
Eq. Alexander, Sidney Robert, Guy's Hospital. / Brown, Frederick Nathaniel, St. Bartholomew's Hospital. / Mariette, Ernest Paul Alphonse, King's College. / Rowell, George, Guy's Hospital.

THIRD CLASS.

Eq. Seville, Charles Frederick, Owens College. / Spencer, Walter George, St. Bartholomew's Hospital. / Trevelyan, Edmond Fauriel, St. Bartholomew's Hospital.

PHYSIOLOGY AND HISTOLOGY.

FIRST CLASS.

Bradford, John Rose (Exhibition and Gold Medal), University College.
Brown, Herbert Henry (Gold Medal), University College.

SECOND CLASS.

Burghard, Frédéric François, Guy's Hospital.
Spencer, Walter George, St. Bartholomew's Hospital.

THIRD CLASS.

Luff, Arthur Pearson, St. Mary's Hospital.
Bahadhurji, Kaikhosro Nasarvanji, University College.
Alexander, Sidney Robert, Guy's Hospital.
Eq. Lindow, Albert, King's College. / Seville, Charles Frederick, Owens College.
Smith, John Anderson, St. Bartholomew's Hospital.

* Obtained the number of marks qualifying for the Exhibition and Medal.
† Obtained the number of marks qualifying for a Medal.

BRITISH MEDICAL SERVICE.—The following is a list of candidates who were successful for appointments as Surgeons in this service at the competitive examination in London on Aug. 11th:—

	Marks.		Marks.
J. R. Forrest	2475	C. W. Johnson	2100
M. W. Russell	2395	W. E. Berryman	2100
W. R. de Morinni	2370	A. T. J. Lilly	2080
B. F. Zimmermann	2355	R. Caldwell	2075
A. F. Stace	2340	C. C. Reilly	2065
A. Stables	2295	S. E. Duncan	2060
J. F. E. McCraith	2285	J. Maher	2030
E. A. C. Smith	2265	A. Perry	2030
W. M. Hewson	2210	S. M. Cordozo	2010
G. E. Moffet	2210	A. de C. Scanlan	2000
H. A. Haines	2185	H. W. James	1990
J. D. Moir	2175	R. Trevor	1990
R. Crofts	2150	H. P. James	1970
G. M. Dobson	2140	W. Turner	1970
G. E. Hale	2130	B. O. W. Norton	1960

INDIAN MEDICAL SERVICE.—The following is a list of candidates for appointments in this service who were successful at the competitive examination held at Burlington House on Aug. 11th and following days. Fifteen candidates competed for five appointments; all were reported qualified:

	Marks.		Marks.
D. Prain	2625	U. N. Mukerji	2411
A. T. Bown	2610	W. L. Price	2378
J. T. W. Leslie	2560		

NAVAL MEDICAL SERVICE.—At the competition for commissions in this Service, held on Aug. 11th and following days, in the Hall of the University of London, Burlington-gardens, the undermentioned gentlemen were the successful candidates:—

	Marks.		Marks.
Von Tunzelmann	2375	A. B. Murdoch	2040
E. B. Townsend	2310	T. Dunlop	2030
A. G. Wildey	2295	S. Johnson	2030
P. B. Handyside	2200	G. A. Dresper	2000
H. R. Osborne	2170	W. H. O'Meara	1940
J. M. Rogers	2150	W. W. Jacobs	1910
C. L. Nolan	2135	A. F. Harper	1900
H. F. D. Stephens	2135	H. W. A. Burke	1855
F. H. Julyan	2095	E. R. D. Fasken	1840
E. C. Ward	2090	J. C. F. Whicher	1840
W. R. M. Young	2085	A. G. Andrews	1820
G. L. Baker	2064	A. S. Nance	1820
H. W. G. Doyne	2050	E. St. M. Nepean	1820

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 21st:—

Alcock, Samuel King, Sytch House, Burslem.
Coker, Owen Cole, Uxbridge-road.
Heath, Charles Joseph, Cromwell-road.
Hughes, Edgar Alfred, Onslow-gardens.
Pemberton, John Oliver, Lawrence-terrace, Tidal Basin.
Piggott, Frederick Cecil Holman, Ormond House, Richmond.

The following gentleman also on the same day passed the Primary Professional Examination:—

Samuel Gordon Smith, University College Hospital.

Digitized by Google

At the recent examination for the prizes in Materia Medica and Pharmaceutical Chemistry given annually to medical students by the Society of Apothecaries, the successful candidates were adjudged to be as follows:—

1st.—John Henry Garrett, University College: Gold Medal.
2nd.—Henry Hamilton, Bristol School of Medicine: Silver Medal and Books.

MEDICAL MAGISTRATE.—Mr. John Ferra Watson, M.R.C.S., has been placed on the Commission of the Peace for the City of Norwich.

TWO cases of maltreatment of lunatics by attendants have been under judicial investigation this week—one in Kent, the other in Dumfries. In the former the defendant was convicted; in the latter the charge was not proven.

SHEFFIELD GENERAL INFIRMARY.—On Wednesday last the new wing of this infirmary was formally opened. The new structure has a separate entrance, but is connected with the main building by a corridor. Its cost is under £5500, the whole of which, with the exception of some £600, has already been raised.

THE HAMPSTEAD SMALL-POX HOSPITAL.—The memorial recently adopted at a meeting of ratepayers of the parish of St. John, Hampstead, asking that an injunction be moved for to restrain the Metropolitan Asylums Board from the further use of the Hampstead Small-pox Hospital, was presented to the vestry on the 14th inst. After some discussion, the matter was referred to the Sanitary Committee for consideration and report.

THE LATE DR. CUOLAHAN.—At the meeting of the St. Olave's Board of Guardians, on the 21st inst., the clerk was directed to write a letter, expressing the sympathy of the board for the widow and family of the late Dr. Cuolahan, one of the medical officers of the union, who died very suddenly on the previous day. For twelve years the deceased had served the board most faithfully, and only two hours before his death was engaged in the performance of his duties.

HOSPITAL SATURDAY FUND.—On the 26th inst. meetings were held in various parts of London to devise the best means of augmenting the resources of this fund, and of consequently extending its utility. Amongst the different means it was resolved to follow are church parades and sermons on behalf of the fund. Facilities will be afforded for the purposes of the street collection at Marlborough House, the Health Exhibition, Crystal Palace, and other places of public resort.

EXETER HOSPITAL SATURDAY.—For the Devon and Exeter Hospital, the Hospital Saturday Committee at Exeter collected last year £300. In return they had a right to occupy eight beds as patients; and if these were always engaged, it would represent an annual cost of £4200. Some of the governors having recently expressed an opinion that it was not worth their while to continue to receive the Hospital Saturday subscription, at a meeting of the committee of the fund on the 24th inst., the expression of such a spirit by the governors was very warmly condemned, and it was decided to communicate with the authorities, so as to determine whether or not the subscription to the hospital should be continued or devoted to some other institution of interest to the subscribers.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ADKINS, GEORGE, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health to the Plympton St. Mary Union Rural Sanitary District till July 20th, 1887.

BERRY, THOMAS FOLEY, F.R.C.S.I., L.M.Dub., has been appointed Medical Officer to the Workhouse, Enniskillen Union.

CAIGER, F. F., M.B., B.S., M.R.C.S., L.R.C.P., has been appointed Resident House-Physician to St. Thomas's Hospital.

CLARKE, JAMES, M.D.Q.U.I., Surgeon Bengal Army, has been appointed Resident Physician to the Eden Hospital for Diseases of Women and Children, Calcutta.

FOTTRELL, W. J., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Resident Surgeon to the Jervis-street Hospital, Dublin, vice Chance.

GREEN, C. D., M.R.C.S., L.R.C.P., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

GREENSILL, J. NICHOLAS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, Martley Union.

GUY, WILLIAM, L.R.C.S.Ed., has been appointed Medical Officer for the Gosforth District of the Whitehaven Union, vice Parker.

HUDSON, Mr. ERNEST, has been appointed Senior House-Surgeon to the Royal London (Moorfields) Ophthalmic Hospital.

HUDSON, HUBERT ERNEST, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Sixth District of the Battle Union, vice Duke.

HULL, W., M.B., M.R.C.S., L.R.C.P., has been appointed Resident Accoucheur to St. Thomas's Hospital.

JOHNSTON, G. D., M.R.C.S., L.R.C.P., has been appointed Resident House-Physician to St. Thomas's Hospital.

JOSEPH, J. RAPHAEL, L.F.P.S.Glasg., L.M., L.S.A.Lond., late Surgeon-Superintendent Queensland Emigration Service, has been appointed Resident Surgeon to the Hospital for Pacific Islanders in the Maryborough District, Queensland.

KEARNEY, MATHEW, L.R.C.S.I., has been appointed Medical Officer to the Dundalk Workhouse.

LAWSON, R., M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Physician to St. Thomas's Hospital.

LYON, T. GLOVER, M.R.C.S., L.R.C.P., has been reappointed Clinical Assistant in the Skin and Ear Department, St. Thomas's Hospital.

MACKENZIE, H. W. G., M.A., M.B., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat, St. Thomas's Hospital.

OXFORD, J., M.R.C.S., L.R.C.P., L.S.A.Lond., has been appointed House-Surgeon to St. Thomas's Hospital.

RICHARDS, WILLIAM, M.B., C.M.Ed., has been appointed House-Surgeon to the Queen's Hospital, Birmingham, vice Charles Sanders, M.B.Lond., resigned.

ROBINSON, H. B., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to St. Thomas's Hospital.

ROWLANDS, HUGH PUGH, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Llanegryn District of the Dolgelly Union, and for the Towyn District of the Machynlleth Union.

RYAN, JAMES D., L. & L.M.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Dungarvan Dispensary District, co. Wicklow.

STONE, F. W. S., M.R.C.S., L.R.C.P., has been reappointed Non-resident House-Physician to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

DUDLEY.—On the 18th inst., at the Royal Naval Hospital, Lisbon, the wife of John Dudley, M.B., B.A., Surgeon R.N., of a son.

DUKE.—On the 25th inst., at 9, Cornwall-road, Westbourne-park, W., the wife of G. Amos Duke, M.R.C.S.Eng., L.S.A.Lond., of a daughter.

MASTERS.—On the 12th inst., at Westhall House, Brook-green, West Kensington, the wife of J. Alfred Masters, L.R.C.P.Lond., &c., of twin daughters.

MULLIN.—On the 21st inst., at Miskin-street, Cathays, Cardiff, the wife of James Mullin, M.A., M.D., of a daughter.

MARRIAGES.

GABB—PRICE.—On the 20th inst., at St. Anne's Church, Bewdley, by the Rev. W. O. Parker Ford, M.A., Vicar, assisted by the Rev. H. H. Winnington Ingram, M.A., Rector of Ribbesford, J. Percy A. Gabb, M.D.Lond., Guildford, Surrey, eldest son of John Gabb, Surgeon, Bewdley, to Ada, only daughter of Samuel Price, J.P., Bewdley.

HERRON—BATHURST.—On the 21st inst., at St. Mark's Church, West Hackney, James Herron, M.D., to Sarah Elizabeth (Bess), only daughter of the late H. M. Bathurst, Broseley, Shropshire.

JOHNSTON—SMITH.—On the 20th inst., at St. John's Church, Dronfield, by the father of the bride, assisted by the Rev. J. T. F. Aldred, Vicar of Dore, Rev. A. E. Auchinleck, Rector of Car-Colston, and the Rev. E. S. Rounds, Curate of St. John's, Dronfield, John Somerville Johnston, Physician and Surgeon, Spital Hill, Sheffield, to Frances Mary (Fannie) only daughter of the Rev. W. H. Smith, M.A., Vicar of Dronfield.

SYDNEY—HORNSBY.—On the 26th inst., at the Parish Church, Bedfont, Middlesex, by the Rev. Morley B. Saunders, uncle of the bride, Henry Sydney, M.D., of Townall Gardens, Hounslow, to Ellen Isabel, third daughter of the late Colonel H. A. Hornsby, 2nd Madras E.L.I.

DEATHS.

CHAMBERS.—On the 21st inst., at Margate, Frederick Chambers, L.S.A.Lond., J.P., aged 83.

EVERETT.—On the 21st inst., at Sydenham, David Everett, F.R.C.S., late of Worcester, aged 66.

HAVERS.—On the 20th inst., at White Hill, Great Berkhampsted, Herts, John Havers, F.R.C.S., in his 70th year.

HILLMAN.—On the 19th inst., at Beech House, Charmouth, Dorset, William Hillman, Brigade Surgeon A.M.D. (retired), youngest son of the late Robert Hillman, of Lyme Regis, Dorset, aged 51.

PEAR.—On the 21st inst., at his residence, Park-crescent, Brighton, Geoffery Pear, M.D., late of Windsor, 78.

WESTMACOTT.—On the 23rd inst., John Guise Westmacott, M.D., L.R.C.S.Edin., of Howley House, Maida-hill, aged 78.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

NEW HOUSES.

THE *Gesundheit* quotes a proposal drawn up by a Magdeburg society for defining the period during which new houses should be allowed to dry before being inhabited. It is suggested that if the building has been roofed during the winter months (Oct. 1st to April 1st) it should be allowed to dry for four months, while three months would suffice at other times of the year. There should be at least eight weeks between the completion of the internal plastering and the beginning of the occupation. In special cases, where technical and medical experts agreed that the rooms (as ascertained by hygroscopic observation) were fit for habitation, it would be optional for building inspectors to shorten the above-named period from three to two months.

"RUPTURE OF THE COVERINGS OF AN INGUINAL HERNIA."

To the Editor of THE LANCET.

SIR,—With regard to Mr. Bernard Pitts' letter relative to the above in your issue of last week, I may mention that I believe the correctness of the man's statement, for the following reasons. I myself saw the cab drive up to the hospital, and saw the man leave it unaided and alone; and the manner in which he walked into the hospital (ten or twelve yards), without any apparent difficulty, proved there was no physical reason why he could not have walked the distance specified. That he did see a surgeon, or someone at the surgery, there was no denying, for there was the lint wrapped round the parts. Judging the distance from where he said the rupture took place to the surgery, I do not think a quarter of a mile was any exaggeration.

I am, Sir, yours truly,

Brockley, S.E., Aug. 27th, 1884. W. MILNE ANDERSON.

M.R.C.S. (St. Leonards).—The cases, as stated, are not parallel. An unregistered practitioner is liable to a penalty for taking or using a title implying that he is registered, and he cannot recover charges in a court of law.

Miss Richardson is referred to our advertising columns, and to a letter which appears in our present number.

Rev. F. Smith.—It would be against our rules to publish a letter of the kind.

ACUTE MANIA IN CHILDREN.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers tell me of any recorded cases of acute mania occurring in a child of five years. If so, I should be glad to know where I could see such records.—Yours truly,

HARDING H. TOMKINS, M.R.C.S.,

Infirmary for Children, Liverpool, Assistant House-Surgeon.

Aug. 26th, 1884.

SEWING MACHINE WORK.

THE question of the effect upon the system of continuously working the sewing machine as an employment has lately been receiving attention in Germany. Herr Eulenburg, a leading Prussian official, has written in vindication of the machine, quoting Dr. Blaschka's testimony in its favour. Dr. Ohausen, who was connected with the Berlin Hygienic Exhibition of last year, has expressed the opinion that the sewing machine does away with the principal disadvantage of hand needle-work—the continued bent position of the worker. Only beginners at the sewing machine bend forward, those who have learned its use being able to maintain a healthy position of the body. The movement of the foot he considers beneficial to the organism, as it encourages circulation. The movements of the body in arranging and holding the work are, he thinks, such as to resemble in a certain degree a gymnastic exercise. When carried on in good air the working of the sewing machine is of advantage to the digestive and respiratory organs. Importance is attached to the kind of chair used, so that it may readily accommodate itself to the movements of the body. The garments should on no account be worn tight. Dr. Ohausen has found no consumptive tendency amongst the many sewing machine workers he has attended, and considers the work may even neutralise a hereditary disposition of that kind.

Mr. James Cheese.—Such specimens may be obtained from Mr. A. Cole, Notting-hill; from Messrs. Beck, 68, Cornhill; and from other microscopical dealers.

SKILLED NURSING.

To the Editor of THE LANCET.

SIR,—Everyone knows in case of illness the comfort of skilled and competent nursing; but until the need for a nurse arises few persons are aware that there is any difficulty in at once securing a first-rate one, or have any idea of the disadvantages with which this most useful class has to contend.

A nurse must spend no inconsiderable amount of both time and money ere she attains proficiency; and when this is accomplished, how is she to obtain remunerative employment? She must either become an inmate of a home, or a member of the non-resident staff attached to an institute, or she must trust to private recommendation. In the first case she is boarded, lodged, and paid £20, or at most £25, a year. She is sent out as patients apply at the home, and may be in constant employment; but her earnings, whether small or great, are entirely forfeited to the funds of the home. Thus the nurse uses her skill and exhausts her strength for a bare subsistence, and it is evident can make no provision for old age or failing health. If she joins the out-door staff, she has, when out of work, to provide for herself, and when employed the rate of pay is fixed by the institute, and one-half of it, in some cases even more, is claimed by the home. What chance is there that the nurse can lay by any part of her earnings? Last comes private recommendation; and to a few, but only to a very few, this proves an El Dorado. A doctor is struck by the tenderness and skill of a nurse, notes her name and address, places her at once with another patient, and, fortunately for the nurse, gets her name and capabilities well imprinted on his memory, so that when asked to recommend a nurse, "Nurse ——, 14, —— street," immediately occurs to him, and, in consequence, she is often applied for when already engaged. But the doctor's busy brain cannot retain several addresses, though he is sure he knows of many good nurses. If again applied to, he is very sorry Nurse —— is unavailable, but assures the applicant that some one else can be obtained from the homes. The case of the nurse seems hard enough as regards payment; but she is also harassed by numerous restrictions. Her testimonials must be deposited at the home, and are thus useless to obtain an engagement, except through that medium, and she is forbidden to be transferred from one patient to another without the intervention of the institute—in fact, it seems decided that the nurse shall be debarred from most of the advantages her profession would naturally give her.

Some physicians, realising the hardships of the case, have suggested to us to open an institute for first-class nurses, through which, by abolishing all vexatious restrictions and excessive payments, they may reap the benefit of their own toil, and be enabled to save a portion of their earnings for the time of need. All means taken to free the nurse from personal anxiety, every inducement that can be offered to increase her liking for her work, must conduce to the welfare and comfort of her patients; and it is therefore in the interests of all sufferers that we would appeal to the public to support this endeavour to benefit a miserably underpaid and most deserving class.

I am, Sir, yours obediently,

126, Regent-street, Aug. 21st, 1884. E. FAITHFULL.

Vox Medicinæ.—It would be hardly fair to insert our correspondent's letter without the name of the writer being attached thereto.

A QUERY.

To the Editor of THE LANCET.

SIR,—I shall feel obliged if some of your readers will tell me of an institution in which a dumb child, seven years old, of defective intellect, could be received either gratuitously or by payment of a small sum.

I am, Sir, yours truly,

Aug. 27th, 1884. MEDICUS RUSTICUS.

Digitized by Google

H. B. S (Bristol).—In Continental Europe during the Middle Ages, and in England down to the time of Queen Elizabeth (see Sir Walter Scott's "Kenilworth," chapter xiv.), the physician was frequently called an artist. In German the word in this sense still survives in "arzt" (physician), which is an abbreviation of "artista," which, in turn, is itself a Middle High German derivative from the Latin "ars."

Forvet.—The point suggested has certainly not been overlooked.

FUNGI AND CHOLERA.

To the Editor of THE LANCET.

SIR,—As a fungus eater, grower, and observer, I desire to make a few suggestions derived from personal experiment and observation. My reason for communicating anything calculated to imply impertinence and to deprive me of a later honour is, that my suggestions may give a wider scope and basis to those who are making cholera their study. It, moreover, removes the burning germ question into the cooler regions of general biology.

1. Some of the symptoms of cholera are analogous to those produced by the genus agaricus—namely, to those which act by an alkaloid, such as muscarin, and not by an irritant resin. 2. Many micrococci, bacilli, and leptothrix forms are identical; penicilli, toruli, and saprolegnaceæ are identical; and all these, if not identical, are closely related in their physiology. 3. Chemical products in penicillum are in many cases the same as those in agaricus; moreover, the movements are common to the sporangia of both, these movements being related to the escape of the nuclei or spores, and apparently absorption of water. 4. The chemical principle occurring in the sporangia almost constantly makes up a large portion of the contents of the sporangia of both penicilli and agarics. It is soluble in ether and spirit, separates in feathery crystals and volatilises by heat. The odour is that of oil of amber. 5. I would recall to mind the power fungi have to break up albuminous materials, such as mucin, into crystalline nitrogenous principles. As regards the chemical substance before mentioned, it seems to be the substance from which the metacellulose of the hyphæ is formed. The crystals, moreover, treated by weak oxidisers, show an abundance of micrococcous forms. Whether this arises from impurities I have not yet ascertained.

Hence it is the chemico-physiology of larger fungi which will help to throw light on the chemico-physiology of germs.

I am, Sir, yours faithfully,

St. Thomas's Hospital, Aug. 21st, 1884. S.

A REMARKABLE CASE.

To the Editor of THE LANCET.

SIR,—Perhaps the novelty of the following case may induce you to find space in your journal for its notice.

A man much distressed, and evidently in great pain, came to me the other evening, saying he had a "soda-water bottle in his fundament." Upon at once letting down his trousers (which were covered with blood), I noticed blood trickling from the rectum. On introducing a forefinger into the bowel I could just detect the edge of the mouth of a bottle, and, by inserting the middle finger as well, was able, after some difficulty, and employing all the traction my limited hold permitted, to extract, not an ordinary soda-water bottle, but one which is, I think, used to contain ginger ale, the length of which was seven inches and a quarter, and the circumference seven inches. His story was that, as his bowels had not been opened for more than a week, and as aperients had not acted, some one advised him to open them by means of a bottle, and that in attempting this it had slipped from his grasp, and all his efforts to get it again were unavailing.

I am, Sir, yours obediently,

Finchley, Aug. 27th, 1884. AUG. DIXEY, M.D.

HYDROCELE.

To the Editor of THE LANCET.

SIR,—During the past two years I have met with two cases of hydrocele, of a similar nature to the one described by Dr. H. C. Cameron in THE LANCET of May 10th. One occurred in my own practice, and one in the practice of a friend, who sent me the fluid for examination. In both cases the fluid was similar to that in Dr. Cameron's case. It had the appearance of milk, a neutral reaction, and was coagulated by heat. The microscopical appearances were similar to those of chyle. Sir W. Fergusson's case was presumably one of filarial disease, as similar fluid was found in the other serous cavities, and the urine was chylous. In my case there was no evidence of filarial disease.

I am, Sir, yours truly,

General Hospital, Madras, July 26th, 1884. J. MAITLAND.

CANNULA FOR INJECTING.

To the Editor of THE LANCET.

SIR,—In answer to inquiries, I beg to state that the hollow, blunt, or closed cannula, with an eyelet at the sides like a catheter, left by me at Marseilles, for injecting fluid into the peritoneum, was supplied me by Messrs. Krohne and Sesemann of Duke-street, Manchester-square, from a model, I believe, of Dr. B. W. Richardson's. I fancy a small catheter, male or female, would answer. The whole is then attached to a syringe by an indiarubber tube. A Dieulafoy's aspirator needle answers well for injecting the cellular tissue. Messrs. Krohne and Sesemann supply both for 12s.

I am, Sir, yours faithfully,

London, Aug. 23rd, 1884. CAMERON MACDOWALL.

Medicus.—We see no good to be served by publishing the exceedingly rude letter forwarded to us by our correspondent. We sincerely congratulate him on not securing the services of a locum tenens who could indite such an epistle.

WILL *Constant Reader*, whose letter appeared in our columns on the 16th inst., forward his address, which has been mislaid?

Mr. Knight Treves.—Next week.

Mr. H. B. H. Turner.—We are not publishing the papers in full.

"PREVENTION OF 'HARVEST BUMPS.'"

To the Editor of THE LANCET.

SIR,—If "M.D." will read Dr. Ringer's remarks on Sulphur in his work on "Therapeutics," p. 131, and various comments on this drug, he will be better able to judge whether my recommendation "was seriously meant." I am aware of the disagreeable smell of sulphur, and so recommended lavender water to be added. As "necessity is the mother of invention," fumigations in lodgings, I think, will not be impossible. "M.D." fails to comment vividly on the usage of carbolic soap. I may, however, refer him to the researches of the late Sir Erasmus Wilson, and Drs. Roberts of Manchester, Anderson, and Hebra, and he will find thereby that opinion differs. He also seems to ignore the fact that a family going for a holiday to the seaside need not trouble themselves about, or provide themselves with, all the means mentioned in my letter, as at all seaside places and health-resorts plenty of chemists are to be found. Harvest bumps seem more prevalent in the country than at the seaside. Seaside bumps, I think, therefore belong to a different nomenclature of the acarus autumnalis, as described by Professors Owen and Latreille.

I am, Sir, yours obediently,

Woburn-place, Aug. 25th, 1884. C. S. TAYLOR, M.D., M.Ch., B.Sc.

Albuminuria.—We should advise the perusal of Senator's article on the Hygiene of Albuminuria, published in the *Berliner Klinische Wochenschrift* for 1882, vol. ii.

X. X.—A list of public vaccinators authorised to grant certificates of proficiency in vaccination is issued by the Local Government Board.

Mr. Norman.—We do not prescribe.

"THE LONDON UNIVERSITY PRELIMINARY SCIENTIFIC EXAMINATION."

To the Editor of THE LANCET.

SIR,—The Censor of the Royal College of Physicians deserves the best thanks of students and their guardians or parents for his exposure of the absurd and cruel examination as regards Physics at the late Preliminary Science Examination of the London University. My ward informs me that, although a pupil of Professor Cary Foster, and regularly attending his lectures, he was never taught some of the subjects referred to in the questions. As the Professor was paid for imparting knowledge on subjects relating to the examination of which he was one of two examiners, I think he failed to carry out his duties; and surely it would have been but fair to have given questions which tested the student's knowledge of what his Professor had taught him. It appears to me that it would be a great waste of a medical student's time, to devote so much of it as would be required to make him proficient in an outside subject, such as Physics, if the examinations are to be conducted in a like manner as the last was; and I trust the authorities will exercise their discretion in prohibiting such an unfair set of questions in future.

I am, Sir, yours truly,

Aug. 23rd, 1884. AN OLD SURGEON.

Mr. William A. Duncan.—Zur Frage der Behandlung der Uterus-carcinome, Wiener Klinik, 1882.

Mr. J. B. Harrison.—Either, provided the vaccinifer is healthy.

CASE IN DENTAL PRACTICE.

To the Editor of THE LANCET.

SIR,—The following case, being of unusual occurrence, will perhaps be deemed of sufficient interest to merit a place in your columns.

A patient aged fifty-five, the widow of a physician, had complained of pain and deafness on the left ear for about three years, for which she had been treated by several medical men, one of whom at last advised her to consult an aurist. Previous to doing so she came to me, on Aug. 11th, complaining of pain in an upper canine, at the same time mentioning the above circumstances. This tooth was extensively decayed, and the pulp cavity full of pus, but with no extensive peridental mischief. Thinking this a possible cause of the deafness (no other tooth or stump being on that side), I advised its removal, which I did under gas on the same day as the patient visited me. Upon returning next day she assured me that she had felt no further pain or faintness in the ear, and the deafness was quite cured."

I am, Sir, yours truly,

PERCY MAY, M.R.C.S., L.D.S. Ed.

Endsleigh-gardens, N.W., Aug. 22nd, 1884.

M.D.—Either Cassell's or (a much larger work) Wood's Household Practice of Medicine (London: Sampson Low, Marston, and Co.).

A Seeker of Fair Play has not enclosed his card.

ERRATUM.—Under the heading "Stray Notes on the Congress," in our issue of last week, p. 336, for Professor "Panum" read *Plank*, as President of the Surgical Section.

SUMMARY OF A

Lecture

ON THE

TREATMENT OF LUNG TUBERCLE.

Delivered at the City of London Hospital for Diseases of the Chest, on July 2nd, 1884,

BY G. A. HERON, M.D.,

PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—In dealing with the subject of the treatment of lung tubercle, it is not my intention to go into details concerning all the modes of treating that disease which are in general use. To do that would require much more time than we have at our disposal; and, indeed, I much doubt whether any attempt of the kind would be really useful. The history of the treatment of consumption, remarkable though it is in many respects, does not, I think, strike one who studies it as being the record of a great triumph of medical science over disease. The fact that many different remedies are now employed in the effort to combat this disease proves, that no one remedy can be implicitly relied upon for good results in all cases. It falls to the lot of medical men, in their every-day work, to make many curious experiences; and amongst these experiences there are some unpleasant ones. Everyone who practises medicine will certainly make two unpleasant experiences before he has been long engaged in the treatment of disease. It will often happen to each one of us to stand by the bedside of some poor sufferer, whose every look, whose every word, speaks eloquently of the hopeful trust he has placed in the skill of the man to whom he has turned for help in his time of sore need. How sad and how bitter it is, in such a case, for the physician to find that, beyond the shadow of a doubt, medical science can do nothing to turn death away from his patient! The knowledge that the conditions are few in which, even in the most desperate cases, suffering cannot be lessened, and the way to death made easier by the use of remedies, does not bring very much consolation with it to the physician. There is bitterness enough for us in such an experience as that, without, as now and then happens, the additional sting of hearing, after the case has ended, that certain of the patient's friends had felt sure that had Dr. So-and-so been consulted things might have turned out very differently for the sick man: that is one of two unpleasant experiences certain to happen to us all. It will also certainly happen to us all to receive the expression of the heartfelt gratitude of a patient, who tells us that he owes his life to our efforts, and that, but for our able treatment of his case, he would have been lost to those who are nearest and dearest to him; and while our patient is pouring out his eager thanks, a horrible thought may arise in us, and we may be obliged to confess to ourselves and to him, that we have very good grounds for doubting whether our interference in his case has been of so high a value as he believes it to have been. Now, I think that those of us who are often asked to direct the treatment of consumption are especially apt to suffer both of these painful experiences, and I do not know which of the two is the more distressing.

It is important to bear in mind that the progress of consumption is rarely one of rapid decline. In the majority of instances lung tubercle progresses by leaps and bounds, interspersed with frequent, and sometimes prolonged, periods of apparent arrest of the disease. That fact must never be forgotten when one is endeavouring to estimate the value of any given line of treatment. Until we can point to a long series of cases where permanent arrest of the disease has practically always followed the use of certain remedies, the most that we are entitled to say of any treatment of lung tubercle is that its use is often followed by improvement in the patient's condition. That that improvement is occasionally the beginning of the permanent arrest of the disease, and of the consequent restoration of the patient to health, is a matter within the experience of everyone who has seen much of lung tubercle. But if, in such a happy event, we attempt to make an estimate of the value of the treatment we have used, we are at once confronted with the fact, that in very many cases no good whatever—or practically none—has resulted from this same treatment; and also that failure, so far as permanent arrest of the disease is concerned, has, in the majority of cases, followed the use of the treatment under consideration. Let us suppose that we send a hundred patients abroad to spend the winter in a mountain climate, having previously detected in their expectoration the bacillus of tubercle. We select these persons with due regard to those conditions of disease which, it is said, ought to mark cases as being of the type most likely to benefit from a residence in such a climate. Well, of the hundred a considerable majority will return to England distinctly the better for their trip to the mountains. Amongst the majority will be found a few who, judged of by their appearance, are literally "pictures of good health." We shall probably see amongst them a young man who left home pale, emaciated, feeble, tormented by a constant cough, distressed by profuse night sweats, and who, it may be, had suffered from the effects of lung hæmorrhage, more or less severely. Instead of the emaciated frame, the pale face, and the stooping shoulders, which characterised this young man's appearance before he left home, we see a sun-browned face, an erect and seemingly vigorous frame, and we have the pleasure of hearing that our patient seldom or perhaps practically never coughs, and that night sweats and blood spitting have long since ceased to trouble him. Fortunately it does occasionally happen that such a patient seems to have been permanently cured, and an examination of his chest shows us that the evidences of active disease have disappeared. But in the majority of such hopeful-looking cases we find, on examination, that in spite of the great and strikingly evident improvement in our patient's appearance, the cavity which he had in one of his lungs when he left home is not healing, and it may even be larger than it was when we last saw him. In short, though his general health has benefited vastly, new colonies of bacilli have made fresh lodgments in his lungs. The meaning of all this is that our patient's disease has passed into a condition of comparative quiescence, owing, most probably in great part, to the good effects of the climate he has just left. But then, such good results are by no means very common amongst those who spend a winter amongst the mountains. The benefit, as a rule, is less marked, and, even at the best, is too apt to be but temporary. Nor are such benefits to be obtained only from residence at a mountain station. Egypt, Algiers, and many other parts of the Mediterranean littoral, not to speak of Australia, the Cape colony, parts of America, and many other places, can show as good "cures" as can any mountain station. Our own English health resorts are, also, by no means without similar records,—a fact which, it seems to me, is in some danger of being too much overlooked in the present day. The most that can be said in favour of any health resort is, that a majority of the consumptives who frequent it benefit in health as a consequence, and that in many cases the downward course of the disease is retarded. But I submit that we have no proof that permanent cure of lung tubercle is ever wholly owing to climate influence. A large majority of those who are affected with lung tubercle die of that disease whether they go to health resorts or not; and I do not know that it would be very wide of the truth to say that many of those who go abroad, in the hope of being cured, would do quite as well at home, where they would be amongst friends who would take care of them, and where they would be spared the pain of separation from the home life and all its comforts. In saying this I am not forgetful of what has been said about the importance of carefully selecting cases before recommending to them residence abroad.

It is a fact which I know could, if necessary, be vouched for by several of my colleagues in this hospital, that apparent recovery from lung tubercle is not unknown in our practice here; and that the cases are not few where years have passed between the first appearance here of the consumptive and the last time that he was seen at the hospital. And we must not forget that the great majority of the people who consult us here are poor, many of them very poor indeed. Change of climate is out of the question for the bulk of these poor people, and many of them live and die in this East-end of London without ever having journeyed so far west as St. Paul's Cathedral. I have often spoken to men and women in this hospital who had never seen Cheapside, had no notion where the Houses of Parliament are, and had not visited, and did not care to visit, Hyde-park. When we know that

Digitized by Google

amongst a class of people so circumstanced and living, in too many instances, amongst most insanitary surroundings, recoveries from lung tubercle are, though rare, not so very rare we must admit that that disease is sometimes apparently cured without the help of a change of air and climate, and without even the advantages of a residence in ordinarily healthy houses.

If, again, we turn to the drug treatment of lung tubercle we find that we can never say to any patient, "Take this, and you will surely find that your health will improve." Good results in abundance can be quoted as having followed the use of, for instance, cod-liver oil in lung tubercle; but equally good results could be quoted, I believe, where soda and gentian had been the only drugs prescribed. And I have no doubt, judging from the results of my own observations, that precisely the same remark may truly be made concerning the use of arsenic, the hypophosphites, and numerous other drugs which have had ascribed to them much success in the treatment of lung tubercle. It is true that in certain cases improved health results after the use of drugs, but that is not known till after the event; and we cannot foretell with certainty that the use of any drug will of necessity be followed by improvement in the health of any consumptive.

It was only about twenty-seven months ago that our knowledge of the cause of tubercular disease received its greatest addition from the genius of a man of whom the whole profession of medicine in every country has good reason to be proud. No sooner did Dr. Robert Koch discover that tubercular disease is due to a living organism than he set to work to search for a remedy for that disease—the most fatal of all the diseases which affect civilised man. Koch did not seek the remedy at the bedside of the consumptive, for he believes that, if such a remedy exists, it will be found in the outcome of experiments conducted in the laboratory and tested at the bedside. He and his assistants were able freely to conduct these experiments, for the great German nation have not yet learned to regard human interests as standing upon a lower level than those of the lower animals.

I propose now to lay before you, as shortly as I can, the results of practical importance which those experiments have established in connexion with our present purpose. I shall quote observations made by Drs. Ernst Schüll and Bernhard Fischer, in the Imperial Health Office in Berlin, whose chief is Dr. Koch. The object that these two gentlemen had in view was the ascertaining of how perfectly to disinfect the excreta of tuberculous patients. With the details of the elaborately exact series of experiments carried out by these observers for that purpose I need not now trouble you. In the end they established these two important facts, amongst others:—1. That a 5 per cent. solution of carbolic acid in water, mixed with an equal bulk of fresh sputum containing a large number of tubercle bacilli, in twenty-four hours destroyed the virulent properties of the sputum. 2. That ten parts of a saturated solution of anilin in water, freshly prepared, mixed with one part of fresh sputum containing a large number of tubercle bacilli, completely sterilised the sputum in twenty-four hours. Drs. Schüll and Fischer established these facts by injecting some of the fresh sputum, before its disinfection, into the bodies of animals, and found that tubercular disease was invariably developed as a consequence in the lungs, liver, and spleen; whereas, after disinfection of the sputum in the way just indicated, no tubercular disease followed its injection into the bodies of animals. Besides carbolic acid and anilin, several other substances were experimented with by Drs. Schüll and Fischer, amongst them were some which proved more or less efficient in destroying the virulence of tuberculous sputa. Of these, absolute alcohol gave the best results, for it sterilised one part of the infected sputum with ten parts of absolute alcohol; sterilisation of the sputa was slower. Corrosive sublimate did not yield satisfactory results; for it was found that the animals experimented upon with this substance died of sublimate poisoning when they were subjected to an injection of equal parts of a mixture of tuberculous sputa and 1 in 500 solution of perchloride of mercury. So far as our present knowledge helps us we can only use carbolic acid and anilin in the treatment of lung tuberculosis from these experiments. In the choice of [illegible] acid is limited [illegible] the method of disinfection [illegible] the sputum is [illegible] cost [illegible] [illegible] [illegible]

amount of carbolic acid vapour in the air rather more than 1-1000th of 1 per cent.

Experiment 2.—The vessel was sixteen times refilled with water, which is equal to 0·7 cubic feet of air drawn through the apparatus. Duration of experiment not mentioned. Weight of carbolic acid obtained = 0·1386 grain. Total weight in whole ward room air = 82·02 grains. Volume of carbolic acid vapour at 80° F., corresponding to the weight of acid found, 2·13 c.c., or 0·141 cubic inch. Total volume of vapour in ward air = 84·7 cubic inches. Percentage amount of carbolic acid vapour in the air = not quite 1-1000th of 1 per cent.

These two experiments, which were made with an interval of about a week between them, seem to show that the ward-room air maintains a fairly constant composition at a definite temperature, but, owing to the difficulty of dealing with such a very small quantity of vapour, they must only be taken as of tentative value, for many more experiments would have to be made under varying conditions of temperature &c., before any definite conclusion could be arrived at."[1]

We know very well, from the results of cultivation experiments, that the bacillus of tubercle increases in number with considerable rapidity out of the body, though its exact rate of multiplication is not yet known. We know also, from our observations at the bedside of the consumptive, that the organism forms new colonies with distressing perseverance after it has made its first lodgment in the human lung. When we remember that a mature bacillus contains from two to six spores, and that probably each one of these spores will in its turn become a full-blown organism, and the parent of a numerous progeny; and when, in addition to all that, we call to mind how difficult, and how rarely successful, is any attempt thoroughly to disinfect, or, in Listerian phrase, to "make sweet" a moderately deep wound to which there is easy access from the surface of the body—we can form some estimate of the extreme difficulties that lie before us in our attempts to destroy the growth of the bacillus of tubercle within the lung.

One thing seems clear to me, and that is the absolute necessity of submitting patients night and day, without any intermission, to the action of the vapour of carbolic acid, if we wish to test thoroughly its action in cases of lung tubercle. It must be obvious to everyone, after studying the experiments of Schüll and Fischer, and reading Mr. Ansell's report, that nothing short of strict confinement to the inhalation room by night and by day and for a long period can be of real use in materially impeding the growth of the bacillus in the lungs. It is upon that condition being distinctly accepted by patients that admissions to the inhalation room upstairs are granted. Of course certain short absences from the ward must be allowed, the lavatories being at some little distance from it. During even these short absences the patients are required to wear a respirator, through which they inspire air charged with carbolic acid vapour. Now, I beg you not to misunderstand me in this matter of the respirator. It is with no object of filtering the air or raising its temperature that I have advised the use of the respirator. The sole object that I have in view is to impress upon the patient's mind that he must keep up the supply of carbolic acid vapour without a moment's intermission. Perhaps I may as well now tell you that no case of carbolism has occurred amongst the patients in the ward, and it has been used as an inhalation room since last January. It is almost superfluous to state that the patients' urine has been carefully watched from day to day.

I much regret that the patients who have passed through the inhalation room are too few in number to warrant any special reference to them at present. Those of you who are interested in their clinical history are welcome to go into the ward and see and examine the cases. A journal containing a detailed report of all the cases hitherto submitted to treatment there, by inhalation, is on the ward table, and is, of course, open to your inspection. You can therefore, as practitioners of medicine accustomed to the study of disease, form your own opinions concerning these cases. For my own part, I will only say that I find in the record of these cases sufficient encouragement to pursue still further this line of treatment; and so I, in common with all my colleagues here, was asked to contribute to the course of lectures now being given at this hospital, I thought this subject worthy of your notice, and therefore selected it for consideration to-day, for I cannot shut out from my mind the hope that the road to success in treating consumption, should we ever find it, may be found to lead in the direction which seems to be indicated by Koch's researches.

[1] From the above data it follows that patients in the inhalation room pass seven cubic feet of carbolic acid vapour through their lungs in twenty-four hours.—G. A. HERON.

Clinical Lecture
ON THE
LOCALISATION OF A CEREBRAL CLOT.

By W. R. THOMAS, M.D., M.R.C.P.,
LECTURER ON MEDICINE AT THE SHEFFIELD MEDICAL SCHOOL, AND PHYSICIAN TO THE SHEFFIELD PUBLIC HOSPITAL.

GENTLEMEN,—You have all noticed what a large number of patients we have to treat suffering from hemiplegia owing to cerebral hæmorrhage. Sometimes we find the arm, the leg, and the face paralysed on one side; at other times the arm and leg of one side are affected and the side of the face of the other; in some cases we have aphasia with right hemiplegia; and thus we meet with an endless variety of paralyses and cross paralyses. Some of you have told me that you have found great difficulty in understanding the subject of localisation of cerebral hæmorrhage, so I shall embrace this opportunity, as you have recently seen a large number of these cases, and as your attention has been drawn to them, of saying a few words on the subject, and of endeavouring to make the matter plain to you. I shall not weary you by relating a number of examples, but shall at once proceed to the subject under consideration.

I may remind you that hæmorrhage takes place more frequently into the corpus striatum and optic thalamus on either side than into any other part of the brain. As these are parts of prime importance, receiving fibres which converge here from all parts of the brain, the effect of pressure is very serious. When hæmorrhage takes place into the corpus striatum the arm and leg are generally paralysed. The arm is always (if there be any difference) the more paralysed, and is longer in recovering its healthy state. On the same side as the paralysis of the arm and leg there is also generally a similar affection of the muscles of the face; but the loss of power is not so complete as it is in the extremities. Some say that if the hæmorrhage is great there is partial paralysis of the muscles of the chest and abdomen. Some deny that the muscles of the chest are affected. Dr. Todd says, "it must be an extensive lesion which will paralyse the intercostal and abdominal muscles." The greater the hæmorrhage the more extensive are the symptoms; and it is only in extreme cases that the head and eyes are affected, and even then they are the first to recover. The head seems to be turned to the side corresponding to the seat of the clot, owing, of course, to the paralysis of the muscles of the other side. Both eyes also are turned in the same direction; there is not any squint, but both eyes seem to be turned to one side and slightly upwards. The branches of the middle cerebral artery, which pass up from it through the anterior perforated plate, are those which rupture. Sensation is unaffected in the paralysed parts. The upper part of the arm and leg regains power before the lower part, before the hand and foot. The symptoms vary much according to the part of the corpus striatum affected; but I shall refer to this another time.

Slight hæmorrhages may occur on the most superficial or ventricular surface of the optic thalamus without giving rise to any appreciable symptoms, and it is difficult or almost impossible to say what are the direct symptoms produced by hæmorrhage into the optic thalamus alone, as such hæmorrhage hardly ever occurs. The arterial supply of the corpus striatum and optic thalamus are so intimately connected that hæmorrhage into the one extends more or less into the other, or if it do not extend it exercises pressure. When there is hæmorrhage into the optic thalamus there is anæsthesia more or less on the side opposite to the lesion, with sometimes tonic or clonic spasms of the same parts. There is also invariably paralysis of the opposite side, which no doubt is due to pressure on the corpus striatum. It has been noticed that when hemiplegia is present from hæmorrhage into the corpus striatum, the more posterior the

Digitized by Google

hæmorrhage, or, in other words, the nearer it is to the optic thalamus, the greater the amount of anæsthesia.

Small clots have frequently been met with in the cerebrum which have not produced any symptoms during life, as indeed post-mortem evidence of disease of the cerebrum has been met with where no evident symptoms during life have pointed to such. If the hæmorrhage be great, apoplectic symptoms are present, followed by paralysis; but that is no doubt more dependent on pressure on the subjacent ganglia—i.e., the corpora striata or optic thalami—than on injury to the cerebrum itself. It is astonishing how the brain can tolerate the presence of a small clot, or non-extensive disease, without giving rise to any very evident symptoms during life.

Hæmorrhage into the lateral ventricle is accompanied by coma, steadily increasing. It often occurs in this way. Effusion first takes place into the corpus striatum or optic thalamus, as evinced by hemiplegic symptoms. After a time the bleeding begins again, and then we have ventricular hæmorrhage with its coma, and the coma is frequently preceded by convulsions, which occur at the moment the hæmorrhage takes place.

Hæmorrhage into the under surface of the crus cerebri gives rise to paralysis of motion on the opposite side. Hæmorrhage into the upper surface causes loss of sensation on the side opposite to the lesion. But if the back and inner part is pressed upon, we have not only the hemiplegia, but also paralysis of the muscles supplied by the third nerve on the same side as the lesion—not on the same side as the hemiplegia, because the nerve is pressed upon here before it has entered the brain. These paralyses can only be said to depend on a clot when they commence at the same time; for if they do not, the paralyses may be dependent on other causes, as syphilis.

Lesions in the pons are somewhat more difficult to understand than those I have just described to you, and the symptoms present during life vary according to the position of the clot. For instance, a clot in the upper part of the pons on one side will give rise to paralysis of the face, arm, and leg of the other side; whereas a clot in the lower part of the pons on one side will occasion paralysis of the arm and leg of the side opposite to the lesion, and of the face on the same side as the lesion. The fibres of the portia dura, which enter the pons at its posterior margin between the middle and inferior peduncles, decussate about the middle of the pons as they are passing on to the opposite hemisphere. Keeping this in mind, we can quite understand that a small clot in the lower half of the pons will, because it presses upon the portia dura nerve before it has decussated, of course produce paralysis of the muscles of the face on the same side as the clot, and, because it presses on fibres passing up from the opposite side of the body, which have decussated at the lower part of the medulla oblongata, will produce paralysis of the opposite leg and arm. A clot in the upper part of the pons on one side will produce paralysis of the face, arm, and leg on the opposite side, because all fibres here have decussated—those from the arm and the leg in the medulla oblongata, and those from the face in the pons. We may also find that the fifth nerve is implicated in the same way as the portia dura of the seventh, so that we have not only paralysis of one side of the face, but also anæsthesia, with paralysis of the temporal and masseter muscles. Often, too, there is paralysis of the sixth nerve on the same side; so that there is, in addition to the symptoms already mentioned, an internal squint. Of course, a clot about the middle of the pons on one side may involve fibres which have and fibres which have not decussated, and thus we may find paralysis of both sides of the face. In fact, there are many combinations of paralysis met with, such as paralysis of both sides of the face, of one side of the face and both sides of the body, both sides of the face and one side of the body, the paralysis depending upon the amount and locality of the clot. When the hæmorrhage is very extensive, there is general paralysis of the arms, legs, and all the muscles of the body, with frequently a contracted state of both pupils. This is a state which has often been mistaken for poisoning by opium.

Hæmorrhage into the medulla oblongata is generally fatal, and death is usually instantaneous. It hardly ever gives rise to any symptoms of a chronic character. When there is disease of the medulla oblongata, there is paralysis more or less of the tongue, palate, lips, and vocal cords; but you will remember that extensive hæmorrhage is rapidly fatal.

There are not any distinct symptoms accompanying cerebellar hæmorrhage. There may be hemiplegia or hemianæsthesia on the side of the lesion or on the opposite side; but of course these symptoms are not peculiar to this hæmorrhage. They are probably caused by indirect pressure upon the motor tracts below. Brown-Séquard says that in cerebellar hæmorrhage there is neither facial nor lingual palsy; and severe vomiting or severe pain at the back of the head would point to the cerebellum as being the seat of disease, as they so frequently are present in other diseases of the cerebellum.

ON THE

IMPORTANCE OF ISOLATING SLIGHT AND DOUBTFUL CASES OF SCARLET FEVER.[1]

BY J. S. CAMERON, M.D., B.SC. EDIN.,
HONORARY PHYSICIAN TO THE HUDDERSFIELD INFIRMARY, MEDICAL OFFICER OF HEALTH TO THE BOROUGH, AND MEDICAL OFFICER TO THE BIRKLY FEVER HOSPITAL, HUDDERSFIELD.

I SHALL take it for granted that we are all pretty well of one mind as to the desirability of imposing some artificial check upon the spread of scarlet fever. Most of us, at any rate, are accustomed to regard epidemics as increasing in intensity as they extend. All of us will certainly admit that children of the school-going age are more obnoxious to the infection of scarlet fever than grown-up persons. Very few would hesitate to separate a child with sore-throat, strawberry tongue, red rash, and a temperature of 104° F., from his playmates, and to keep him away till desquamation had ceased. In doing so, we should for the first few days have the cordial coöperation of his parents, and although the coöperation might be less readily granted during the later stages of convalescence, and his friends might not altogether see why the little fellow, well wrapped up, should not be sent in a comfortable first-class compartment to a health resort, when the change would do him so much good, still, when our care has resulted in the escape of the rest of the family from the disease, we shall perhaps have a certain amount even of gratitude from the powers that be. Different is it, however, when we hesitate at all as to the nature of the case. The British parent cannot live in an atmosphere of doubt. The case certainly either is or is not one of scarlet fever; and if we cannot say positively that it is, he concludes, and acts upon the conclusion, that it is not. The object of the present paper is to strengthen the hands of my professional brethren in dealing with impatient parents. I propose, therefore, briefly to narrate three instances which have lately come to my knowledge in which, as it seems to me, there were strong reasons to think that certain doubtful cases of the disease had formed foci of contagion. In each instance my information came in the first place from medical men; in all three cases the delay in giving information was not on the part of the practitioner, but was, I believe, due to the ignorance of the parents as to the real nature of the ailment.

The case I propose to relate first was that of a middle-class day school for girls. One of two sisters attending this school was subject to slight feverish attacks; these had been so frequent and so trifling that her parents had given up sending for their medical man on account of them, and were in the habit of treating her themselves. Her sister slept with her, and continued going backwards and forwards to school during an illness apparently of the usual character. One of the girls in the same class took ill of scarlet fever, and the medical man attending her being also called in to see the girl first mentioned, and who had not made as quick a recovery as usual, found the latter covered by a fine desquamation. He very prudently at once ordered her sister to remain away from school, the schoolroom was disinfected, and fortunately no further case occurred. Had the girl whose sister was attending school recovered rather more quickly, no medical man would most likely have been sent for, and probably one or two other cases would have occurred before a clue to the cause of the outbreak had been obtained.

The next instance I shall give has been already referred to in my report to the sanitary committee of the Corporation

[1] Read before the annual meeting of the Yorkshire Branch of the British Medical Association, held at Huddersfield, June 25th, 1884.

Digitized by Google

for 1883 (p. 14). The cases occurred in children attending the same class in one of our large board schools. Two children, living in houses half a mile apart, were reported ill of scarlet fever, and a few days later one case more occurred in each house. On visiting the school I examined every member of the class to which these children belonged, and obtained from their teacher the names of those members of the class who were or had lately been away from school. One child was actually present in the class-room with a sore-throat, a tongue covered with bead-like papillæ, and free desquamation from the neck. At my request she was sent home, where I saw her again, and whence I sent her, and, a few days later, her younger sister, to the fever hospital. Her ailment had been so slight that she was, I believe, kept away from school only one day on account of it. The commencement of her attack corresponded in time with that of the two cases already mentioned, so that it was necessary to carry the search for the common cause of these cases, one of which proved fatal, yet further back. I will put down the dates of these three cases:—B. B——, the girl last named, aged seven years, sore-throat and retching on Saturday, the 20th, and rash on Sunday. A. M——, aged nine years and nine months, throat dry on Sunday, the 21st; at school on Monday. S. A. H——, aged nine years, at school on Monday, the 22nd; sickly on Tuesday; rash on Wednesday. Leaving out cases which manifested themselves later in other members of the same family and other members of the class, I pass on to what was, I think, the case really infecting those already mentioned.

E. A. C——, a girl, aged eight, had complained of feeling "starved" (which in Yorkshire means a slight rigor), and on Oct. 9th, 1883, as nearly as her mother could remember, she developed a slight rash upon her chest. Her mother seemed to think she had kept her at home on the day of the rash, and it may have been so; but in that case she must have given me the wrong date, for on referring to the school register, I found that she had attended on that day.[1] When I examined her on Oct. 30th she still had the smooth-based, rather red tongue, covered with rounded papillæ of the same colour, like small beads studded on its surface, that one so frequently finds in children who are recovering from scarlet fever. The girl was of course kept away from school, as were also a few other children about whose condition there was some doubt, principally because they had slight sore-throat; and, as far as I can remember, no new case has occurred at that school up to the present time. I feel no moral doubt that this girl was the efficient cause of the disease in her class-mates. Her illness was, however, so slight that even had she been seen by a medical man at the time the case would probably have been regarded as doubtful—too doubtful, very likely, to send into hospital. And yet, as I have said, I cannot doubt that this slight case was the immediate cause of several others, one of which proved fatal.

The remaining instance was even more painful. The first cases heard of were two children in whom there was said to have been no rash, and death was ascribed to nephritis and dropsy. The medical man called in to certify the cause of death kindly drew my attention to the matter, and going with him to inspect the house on Jan. 20th last, we sent two other members of the family to the fever hospital, and within a few days four others followed from houses only a few yards distant in the families of their intimates. A month later I was called to a dirty little "yard," a stone's throw from the house in which the children had died of nephritis. Here I found four new cases of scarlet fever (two of them proved fatal within a few hours) and three convalescents. The illness in the latter dated, in two out of the three cases, four weeks back, and had been so slight that the children ran about the whole time, thereby in all likelihood infecting the four others. No medical man had been called in, not unnaturally, for the children could not be said to be ill. The history of the exposure of these children to the infection in the house where the dropsy cases occurred was clear enough. The two families were on very intimate terms, and constantly visited each other's houses. The three convalescents and three of the four new cases were sent to hospital; the seventh was too ill to be removed. The mother of some children already mentioned as having been taken to hospital had also an attack of nephritis, probably scarlatinal, and was taken into hospital at her own request. Counting her case, but omitting four other clear cases of scarlet fever occurring during the next few weeks within a radius of a quarter of a mile, in which I was, however, unable to trace direct contact with any of the infected persons, may we not conclude that had the first two cases been isolated at once the other fourteen would probably have escaped, and two deaths less would have been registered as from this disease? I should be inclined to seek the cause of the four other cases in infection from those I have mentioned, for (1) no cases had been heard of in that part of the town for some months, and (2) some of them were, I believe, attending the school to which the two children who had scarlet fever without being ill were going until I stopped them. Still, as the evidence was less clear in these cases, we may leave them out. About the other fourteen, the evidence as to the contagion was as clear as it could be, and the cases to which we traced it were not recognised at all as cases of scarlet fever.

These three instances, I think, help to strengthen the evidence as to the infectiousness of slight cases of scarlet fever; of cases so slight or so doubtful as to be difficult to recognise. I think every medical man will agree with me that in view of such cases as the foregoing, and of similar ones which will rise to the mind of every one, it is of the highest importance to isolate slight and even doubtful or suspected cases of this deadly malady.

[1] She was absent, however, according to the register, on the 8th, 12th, 17th, 22nd, and 26th of October, and the last ten or twelve days of September. In the report referred to I find I have called her a girl of twelve. This was done from memory. She was a big, well-grown girl, and looked as old as that, but I find I had put her down in my note-book at the time as eight years of age.

CASE OF

RESUSCITATION AND RECOVERY AFTER APPARENT DEATH BY HANGING.

BY ERNEST W. WHITE, M.B. LOND., M.R.C.P.,
SENIOR ASSISTANT MEDICAL OFFICER TO THE KENT LUNATIC ASYLUM, ASSOCIATE, LATE SCHOLAR, OF KING'S COLLEGE, LONDON.

THE following case, from its hopelessness at the outset, yet ultimate recovery under the duly recognised forms of treatment, is of such interest as to demand publicity, and will afford encouragement to others in moments of doubt.

M. A. S——, aged fifty-three, was admitted into the Kent Lunatic Asylum at Chartham on Oct. 3rd, 1882, suffering from melancholia, the duration of which was stated to have been three months. She had several times attempted suicide by drowning and strangulation. She was on admission ordered a mixture containing morphia and ether thrice daily, to allay her distress. On Oct. 10th she attempted suicide by tying a stocking, which she had secreted about her person, round her neck. Shortly afterwards, with similar intent, she threw herself downstairs. On Jan. 4th, 1883, she attempted to strangle herself with her apron. On the 30th of November following, at 4 P.M., she evaded the attendants, and made her way to the bath-room of No. 1 ward, the door of which had been left unfastened by an attendant. She then suspended herself from a ladder there by means of portions of her dress and underclothing tied together. A patient of No. 1 ward discovered her suspended from the ladder eight minutes after she had last seen her in the adjoining watercloset, and gave the alarm.

The woman was quickly cut down, and the medical officers summoned. In the interval cold affusion was resorted to by the attendant in charge, but the patient was to all appearances dead. The junior assistant medical officer, Mr. J. Reynolds Salter, M.B. Lond., arrived after about three minutes, and at once resorted to artificial respiration by the Silvester method. A minute or so later the medical superintendent and myself joined him. At this time the condition of the patient was as follows. The face presented the appearance known as facies hippocratica; the eyeballs were prominent, the cornea glassy, the pupils widely dilated, not acting to light, and there was no reflex action of the conjunctivæ; the lips were livid, the tongue tumefied, but pallid, the skin ashy pale, the cutaneous tissues apparently devoid of elasticity. There was an oblique depressed mark on the neck, more evident on the left side; the small veins and capillaries of the surface of the body were turgid with coagulating blood; the surface temperature was extremely low. She was pulseless at the wrists and temples. There was no definite beat of the heart recognisable by the stethoscope. There was absolute cessa-

Digitized by Google

tion of all natural respiratory efforts, complete unconsciousness, total abolition of reflex action and motion, and galvanism with the ordinary magneto-electric machine failed to induce muscular contractions. The urine and fæces had been passed involuntarily during or immediately subsequent to the act of suspension. As the stethoscope revealed that but a small amount of air entered the lungs with each artificial inspiration, the tongue was at once drawn well forwards, and retained in that position by an assistant, with the result that air then penetrated to the smaller bronchi. Inspiration and expiration were artifically imitated about ten times to the minute. In performing expiration the chest was thoroughly compressed. The lower extremities were raised, and manual centripetal frictions freely applied. In the intervals of these applications warmth to the extremities was resorted to. About ten minutes from the commencement of artificial respiration we noticed a single weak spasmodic contraction of the diaphragm, the feeblest possible effort at natural respiration. Simultaneously, very distant weak reduplicated cardiac pulsations, numbering about 150 to the minute, became evident to the stethoscope. The reduplication implied that the two sides of the heart were not acting synchronously, owing to obstruction to the pulmonary circulation induced by the asphyxiated state. Artificial respiration was steadily maintained, and during the next half hour spasmodic contractions of the diaphragm occurred at gradually diminishing intervals, from once in three minutes to three or four times a minute. These natural efforts were artificially aided as far as possible. At 5.45 P.M. natural respiration was fairly, though insufficiently established, the skin began to lose its deadly hue, and titillation of the fauces caused weak reflex contractions. Flagellation with wet towels was now freely resorted to, and immediately the natural efforts at respiration were increased to twice their previous number. The administration of a little brandy-and-water by the mouth failed, as the liquid entered the larynx. Ammonia was applied to the nostrils, and the surface temperature was increased by warm applications and clothing. At 6 P.M. artificial respiration was no longer necessary. The heart sounds then numbered 140 to the minute, the right and left heart still acting separately. A very small radial pulse could also be felt. At 6.45 P.M. the woman was put to bed, warmth of surface maintained, and hot coffee and beef-tea given in small quantities. Great restlessness and jactitation set in with the renewal of the circulation in the extremities. An enema of two ounces of strong beef-tea was administered at 10 P.M. The amount of organic effluvium thrown off by the lungs on the re-establishment of respiration was very great and tainted the atmosphere of the room and adjoining ward. The pupils, previously widely dilated, began to contract to light at 11 P.M. Imperfect consciousness returned at 5 A.M. the following day (Dec. 1st), and about an hour later she vomited the contents of the stomach (bread &c. taken on Nov. 30th). Small quantities of beef-tea were given by the mouth during the night. At 9 A.M. air entered the lungs freely, and there were no symptoms of pulmonary engorgement beyond slight basic hypostasis; the pulse remained at 140 and the heart sounds reduplicated; she was semi-conscious, very drowsy; in a state of mental torpor, with confused ideas when roused, and she complained of rheumatic-like pains all over her. The temperature was 100·2°; the facial expression more natural; the tongue remained somewhat swollen and sore; she was no longer restless; she took tea, beef-tea, milk, &c., well; the functions of the secreting organs were being restored; she perspired freely; had micturated; the mucous membrane of the mouth was moist, and there was a tendency to tears without corresponding mental depression. The patient was ordered a mixture of ether and digitalis every four hours. On December 2nd the pulse was 136, and the heart sounds reduplicated. The following day she was given bromide of potassium in place of the ether in the digitalis mixture. On the 4th the pulse was 126; reduplication gone. On the 6th the pulse was 82, and the temperature fell with the pulse rate. She was well enough to get into the ward for a few hours. Her memory, especially for recent events, was at that time greatly impaired. On the 12th she still complained of muscular pains like those of rheumatism. Apart from that she was enjoying good bodily health.

A curious fact in connexion with this case is that since this attempt at suicide she has steadily improved mentally, has lost her delusions, is cheerful, and employs herself usefully with her needle. She converses rationally, and tells me she recollects the impulse by which she was led to hang herself, and remembers the act of suspension; but from that time her memory is a blank, until two days subsequently, when her husband came to see her, and when she expressed great grief at having been guilty of such a deed. Her bodily health is now (June 30th, 1884) more robust than formerly, and she is on the road to mental convalescence.

Remarks.—The successful issue of this case leads me to draw the following inferences:—1. That in cases of suspended animation similar to the above there is no symptom by which apparent can be distinguished from real death. 2. That in artificial respiration alone do we possess the means of restoring animation when life is apparently extinct from asphyxia, and that, with the tongue drawn well forwards and retained there by the hand or an elastic band, the Silvester method is complete and effective. 3. That artificial respiration may be necessary for two hours or more before the restoration of adequate natural efforts, and that the performance of the movements ten times to the minute is amply sufficient, and produces a better result than a more rapid rate. 4. That galvanism, ammonia to the nostrils, cold affusion, and stimulants by the mouth, are practically useless in the early stage. 5. That on the re-establishment of the reflex function we possess a powerful auxiliary agent in flagellation with wet towels &c. 6. That centripetal surface frictions and the restoration of the body temperature by warm applications aid recovery. 7. That the heart, if free from organic disease, has great power of overcoming the distension of its right cavities and the obstruction to the pulmonary circulation, although its action may for a time be seriously deranged, as evidenced by reduplication of its sounds. 8. That when the heart's action remains excessively feeble, and the right and left heart fail to contract synchronously, it would be justifiable to open the external jugular vein. 9. That during recovery the lungs are heavily taxed in purifying the vitiated blood, as shown by the excessive amount of organic impurities exhaled. 10. That restlessness and jactitation accompany the restoration of nerve function, and that vomiting occurs with returning consciousness. 11. That pains like those of rheumatism are complained of for some days subsequently, these probably resulting from the sudden arrest of nutrition in the muscles.

Chartham, near Canterbury.

THE PREVENTION OF DENTAL CARIES.[1]

BY HENRY SEWILL, M.R.C.S., L.D.S.

SUMMING up the knowledge which we possess as to the etiology and pathology of caries in the papers which I have recently contributed to the Journal of the British Dental Association, I found that there exists much more than enough of fact—anatomical, physiological, pathological, and experimental—to establish incontrovertibly the following truths with regard to caries.

Caries is a process of disintegration, commencing invariably at the surface, proceeding inwards, and due entirely to external agents; enamel and dentine are perfectly passive under this process, and manifest neither pathological action nor vital reaction of any kind. The predisposing causes of caries are, first, innate structural defects in the teeth, which render them more susceptible to the action of agents; secondly, all such diseases as are accompanied by vitiation of the oral secretions, or which tend to the formation or deposit of acid and the accumulation of products of decomposition within the mouth; and, thirdly, crowding and irregularity of the teeth, due to smallness and malformation of the maxillæ. The direct agents in initiating caries are acids, the products of chemical change and fermentation set up in fragments of organic matter which are commonly present in the mouth and lodged about the teeth. These acids are often assisted in their action by acid mucus secreted by unhealthy gums, acid saliva in some diseases, and acid eructated from the stomach in others.

For any useful discussion of my present subject it is necessary to state at the outset the fundamental facts upon which reliance is placed. Enamel is the starting-place of caries, and with this tissue we are mainly concerned in studying the etiology of the disease. Enamel is a densely hard,

[1] Abstract of a paper read at the meeting of the British Dental Association at Edinburgh, Aug. 29th.

Digitized by Google

almost homogeneous calcareous mass, containing not more than from 1 to 5 per cent. of organic matter. The enamel organ—that portion of a developing tooth from which enamel is formed—consists of epithelial cells, and it retains its epithelial nature throughout the process of calcification. The completed tissue results from direct calcification of the internal layer of cells. Vascular papillæ arising from the contiguous tissue of the dental sac penetrate to a slight depth the external layer of cells and convey nutriment to the developing tissue. On completion of the enamel these external cells with the vascular loops undergo atrophy and disappear. Dentine consists of a homogeneous calcareous matrix with a basis of fibrous tissue, about 28 per cent. of the mass. It is permeated by minute tubes, occupied by fibrils which endow the tissue with sensibility, and which form the sole protoplasmic element in dentine. The bearing of these anatomical and physiological considerations upon my subject depends upon the obvious fact that enamel is totally devoid of any physiological mechanism whereby either vital or pathological changes could be brought about in it, and that whatever changes enamel undergoes are induced by external agencies. Not only is enamel not capable of intrinsic changes, but it is not in relation with any mechanism capable of influencing it from within. To believe in the possibility of nutritive changes in enamel we must first conceive some means by which this calcareous mass, devoid of cellular elements and incapable of imbibition, could assimilate nutritive material when conveyed to it; and we must next imagine the conveyance of new and effete material to and from the vessels of the pulp through the odontoblast layer of the pulp by way of the dentinal fibrils to its destination within the substance of the enamel.

By the end of the twelfth week of intra-uterine life a cap of calcified material may be demonstrated on the pulps of all the temporary teeth. By the sixth month the first permanent molar has advanced to a similar stage of development. By the first month after birth the permanent incisors and canines are advanced to the same degree, and at the third year and twelfth year respectively calcification has commenced in the second molars and wisdom teeth. It is usual to assume that ill-made teeth result from deficient supply of the lime salts which go to build up the tissues. We do not really know whether this is ever actually the case or whether the defect arises always or sometimes from other causes affecting the tooth germ, whereby it is prevented from undergoing the process of conversion; but be this as it may, we can perceive that it would be useless to attempt, directly or indirectly, by medical treatment to influence the formative process, to promote the production of enamel of good quality, after the lapse of the periods named in the different classes of teeth. The one dark spot in our knowledge of the remote causation of caries is found in the first predisposing cause which I have named: inherent structural weakness of the tissues. The dental tissues vary infinitely in strength in different individuals. We meet with well-made teeth, exceptionally it must be confessed, the sound enamel of which tries the steel of our best-tempered chisels; on the other hand, we encounter, and much more frequently, teeth the soundest enamel of which is throughout chalk-like in its softness. Between these extremes all varieties are to be found; and teeth of general defective character often present patches of surface, the enamel of which consists merely of an imperfectly united mass of granules. Similar defective spots are to be found here and there in teeth of better formation. Sometimes enamel fibres at parts are penetrated at their centres by minute tubes, thus making the tissue at such places porous. Defects in quantity are equally variable in extent. Honeycombed teeth have enamel full of small pits and fissures, and there is scarcely a set of teeth to be found in which, here and there, in one or more teeth, an isolated crack or cleft, a solution in the continuity of the tissue, does not exist.

Our knowledge, I repeat, of the origination of mal-development of the dental tissues is very incomplete. We know that vast numbers of individuals in highly civilised states have ill-made teeth; and we know that the quality of the dental tissues varies very much in the different peoples. To instance a few nations in this regard, and to speak somewhat from my own experience, I should place the Scotch as a people in the first rank of dental development, after them I would place the North Germans, thirdly the English, then the French, and lastly the people of the United States. Among the last, I of course only refer to that part of the population native by sufficiently long descent; those upon whom the climate and other forms of evolution have set their mark. There is evidence, although not conclusive, that in all races of advanced civilisation there has been, in later generations, a notable further deterioration in dental development. To account for these circumstances, we have very few solid facts. One at the outset may be recorded—namely, that comparative disuse of the organs of mastication has led in civilised races to decrease in size and strength of the whole apparatus of mastication—jaws, muscles, and teeth. This fact has been quite recently demonstrated by Professor Flower. He shows, as a result of examination and measurement of many thousands of skulls, that there is a gradual diminution in the size of the teeth, from the anthropoid apes, through the lower races of man, to the European. He has constructed a perfect dental index, in which the average size of the teeth of the gorilla being represented by 50·8 and the Tasmanian by 47·5, the European stands at 40·5. It has been plausibly argued that progressive dental deterioration may be accounted for by the overwhelming demands upon the vital powers by the growth of the brain and its increased exercise in modern life. The brain and the jaws are alike fed from the common carotid artery, and, it is urged, the demand for blood by the growing and working brain leads to imperfect supply of the masticatory organs. Again, dental deterioration has been ascribed entirely to improper and imperfect feeding of children, to insufficiency in the food of lime salts, the proper pabulum of the developing teeth. If this were true, the whole osseous system—which is built up of the same chemical constituents as the teeth—must in every case be equally ill-constructed; it would thus be impossible to find a single individual with a solid skeleton, and such cases as so commonly present themselves, a massive bony system in conjunction with faulty dental tissues, would be unknown. Perhaps with one exception there is no modern people displaying general progressive physical degeneration likely to be accompanied by ill-developed teeth. But it must be recollected that there has been among the populations a constant augmentation in the numbers of the physically imperfect. Vast numbers of the phthisical, the scrofulous, the rickety, and the congenitally syphilitic, who would formerly have perished in childhood, are now by science preserved alive, and these imperfect types are all associated with faulty dental development. Least of all among the nations can the people of these islands be suspected of general physical degeneration. On the one hand, no doubt, injury has been caused by the aggregation of great masses of the population in towns, the sanitation of which is imperfect, and in the employment of great numbers of men, women, and children in crowded, ill-ventilated factories. On the other hand, never before were the great bulk of the British so well sheltered, so well clad, and so well provided with food and the smaller luxuries of life; never before was the public health so well cared for, and never before was there more freedom from diseases which leave their mark on the constitution, and lead to degeneracy in the descendants of their victims.

In discussing questions of evolution we must be on our guard against hastily drawn generalisations, and must recollect that vast periods of time are needed to work permanent changes. Admitting that deterioration of the apparatus of mastication and of the dental tissues has advanced in the present and in recent generations, we are not therefore to believe that this decadence is to continue. So long as mastication is an advantage to the race in making the man a better animal, it is absurd to suppose that the forces of evolution will go in the end to produce a toothless man. And the nations are not interfering improperly with natural forces nor retrograding in physical development. To this, however, I believe there is one exception. The French, having adopted almost universally the practice of restricting population by artificial means, are preventing the action of those evolutionary forces, which, given fair play, ensure in the end the survival of the physically fittest as surely now in the nineteenth century as in the ages of primitive man. The French are carrying on what is really a gigantic system of artificial selection, and by ensuring the survival of the least fit progeny are producing a stunted inferior race. The physical deterioration of the French seems almost proved; but there is not evidence to show that their teeth are bad in proportion; and we must not forget a possible fallacy as regards the teeth. The French use their jaws less than any other nation; they are the best cooks in the world, and the whole population, without exception, lives upon the softest food, including bread of the most delicate manufacture. It

Digitized by Google

is puzzling to observe that the teeth of the French are better than those of the Americans, who cannot be accused justly of adopting extensively those vices of civilisation practised by the French. These observations and contradictory facts are intended to show that the cause of dental deterioration—inherent structural weakness of the tissues—is extremely complex. We do not know yet what are all the factors which can possibly go to produce the results which we note.

When we turn from the general consideration of this subject to the narrower question of the association of defective dental tissues with particular diatheses, we find ourselves on firmer ground, and we may take a solid fact to start with—the fact that hereditary syphilis, which seems to interfere with the development of all the structures derived from the epiblast, leads also in many cases to imperfect formation of the tooth tissues. The amount of injury to the developing teeth depends upon the stage of the disease in the affected parent. It is, of course, most common for the father to be the subject of the disease. A woman pregnant by a man suffering from secondary syphilis of recent date will usually either abort in the earlier months or bring forth a dead child about the full term. As the virulence of the disease in the parent abates under treatment or by lapse of time, the mother begins to bring forth living children; these may perish early or may survive in accordance with the extent to which their constitutions are modified by the syphilitic poison. It is a fact, I believe, that only secondary syphilis is transmissible, and thus so soon as that stage in the parents is passed, children, although often unhealthy, will not display signs of specific hereditary taint. In my experience the typical syphilitic tooth described by Mr. Hutchinson (and which must not be confounded with the merely honeycombed tooth), occurs only in children displaying the worst form of hereditary syphilis; but it by no means forms an invariable accompaniment to this condition. Indeed, I have been struck with the rareness of the malformation in children with unequivocal signs of syphilis. I reckon roughly I have not seen it in more than 1 per cent. of cases. I have observed, however, that in every child begotten of syphilitic parents, and even in those cases where no specific symptoms existed, the teeth, although often good in form and colour, have been of imperfect formation, the enamel soft and easily broken down. I have noticed, also, that the children's teeth were, as a rule, markedly inferior to those of the parents; and I am strongly of opinion that children begotten of syphilitic progenitors may often display inherently defective dental tissues as the sole sign of the attenuated taint. Considering that children of the third and fourth generations would inherit the dental characteristics of their parents, hereditary syphilis may be reasonably looked upon as one of the main causes of imperfect development of the dental tissues.

An intimate connexion between dental mal-development and any other diathesis besides the syphilitic cannot be fully demonstrated, yet there are some of these constitutional conditions with which badly made teeth seem more or less associated. My experience goes to show that imperfect dental tissues are found in the majority of cases of scrofula. I would say that ill-made teeth are not at all a constant accompaniment of any form of phthisis, nor are they especially noticeable in a majority of cases in patients of undoubted tubercular tendency. There is one class of patients, however, the subject of phthisis of tubercular origin which almost invariably presents faulty dental tissues. This is the type most frequently found in females, in which there is often, with a fragile form, considerable facial beauty, in which the eyes are large and expressive, the complexion fair, with the blue veins visible beneath the skin. This is the not uncommon type, in which I have invariably found the teeth, although well-shaped and beautiful to look at, covered with the softest enamel. With rickets I have generally found inherently defective teeth. I can in no way associate faulty tooth development either with the rheumatic or gouty constitution. Indeed, with the latter both teeth and jaws are often of unusually massive and solid character.

What general measures can be suggested likely to aid in the prevention of dental deterioration? We, with other reformers, can direct attention to the need of national sanitation in the broadest sense. Syphilis is an affair mainly of police, and will surely be extinguished in this nation when the people are sufficiently educated in science. Scrofula and rickets are mainly poor children's diseases, and are the direct products of filth, darkness, and starvation. The observance of the well-known general laws of health, we may be sure, will tend to produce good teeth in the race, if not in the individual, and among these laws we must insert one inculcating the use of articles of diet that shall give due exercise to the muscles of mastication, and prevent them, and the bones to which they are attached, from wasting.

It may next be asked, Can we, by any treatment, influence beneficially the developing teeth of the fœtus in utero, through a mother the subject of either of the diatheses or cachexiæ which have been named? Little reliance can in most cases be placed upon treatment specifically directed to this end, and we must depend mainly upon measures for the amelioration of the mother's general health, and the eradication of any definite morbid constitutional taint. To show that defective teeth might occasionally result from deficient supply of the necessary pabulum through the mother, Dr. Thorowgood has brought forward several cogent facts. He has pointed out that a hen with a broken bone lays, during the time the fracture is uniting, soft eggs; the earthy salts which should go to harden the shell being needed for the repair of the fracture. In a pregnant woman the union of a fracture is slow; the inference being that the lime salts are all required for the formation of the bones of the fœtus. In presence of these facts a rule may be established that in every case of cachexia during pregnancy, and particularly where there is a tendency to atrophy and bony wasting, there should be administered mineral nutrition, both dietetic and therapeutic. It is difficult to believe that any treatment could influence some cases in which a strong hereditary influence proceeding from the father gives a bias to the process of dental development. A mother with good dental tissues will often bear children with defective teeth, having the closest resemblance in form and structure to those of the father, in whom this may be the sole physical defect. We are ignorant of the actual physiological or pathological causation of defective enamel; but, as uncertainty exists, we had better err on the right side—especially as the error would be harmless—and enforce the rule that in every case in which ill-made tooth tissues are likely to appear, an attempt by diet and therapeutics should be made to supply to the developing tissues the mineral constituents of which they may stand in need. Also the dates at which the classes of teeth are calcified must be borne in mind, and that after the formation of enamel any attempts to prevent caries by improving the quality of that tissue must be futile. The exteriors of the crowns of all the temporary teeth—from caries of which children suffer so much—are fully formed at birth; these teeth can therefore be influenced only through the mother. By this time the first permanent molars and the permanent incisors and canines are so far advanced in development that it is open to doubt whether our further treatment can have any effect upon the enamel of these teeth. There is, however, no difficulty in administering lime to an infant from birth, as lime-water is an admirable aid to the digestion of milk in infancy.

We must recollect that although structural defect in the enamel is a prime factor in the causation of caries, there is another factor as potent—viz., vitiation of the secretions of the mouth. The diseases of our times, unlike those of earlier days, are largely those which give rise to the formation of such agents in the mouth, for many or most of them are either diseases of the digestive organs, or maladies accompanied by disturbance of the functions of digestion. In this way we may account for the prevalence of caries among certain portions of the community whose physique and general health in other respects are not to a corresponding degree inferior, and whose dental tissues are not of the worst structure. For example, the constant presence of dyspeptic troubles in some classes of factory operatives is enough to account for the rapid tooth decay from which they suffer. These people earn good wages, and are well housed and clothed; but their occupation is sedentary, their food is usually ill-cooked and too solid and coarse; they drink bad beer and coarse spirit, and the result is chronic dyspepsia. This disease is so common in some communities that it is regarded as one of those evils from which there is no escape. When speaking of the association of ill-made dental tissues with certain diatheses, I was not unmindful that some of these diatheses have also as a common accompaniment vitiation of the secretions of the mouth. Thus one type of scrofulous subject—that with coarse features, muddy complexion, and long thick upper lip, has usually a chronic condition of congested oral mucous

Digitized by Google

membrane with secretion of viscid mucus and saliva. Rickets, again, is often preceded and attended by a virulent form of acid dyspepsia.

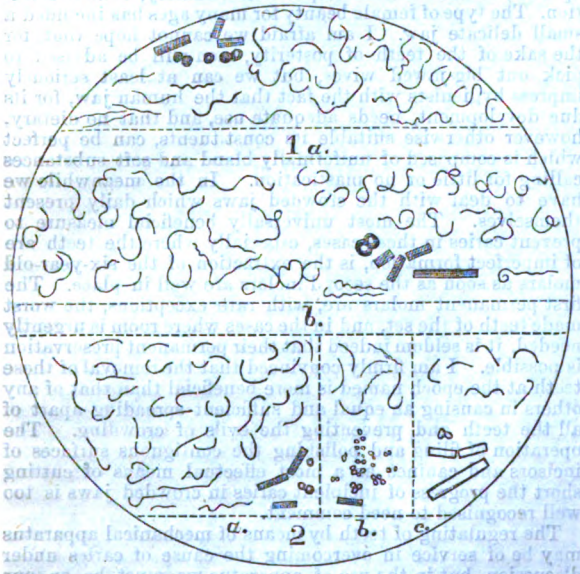
The broad facts now before us are—first, that without acid, without vitiation of the secretions of the mouth, caries is impossible; and secondly, that acid capable of dissolving enamel—and of more rapidly dissolving enamel in proportion as the tissue is soft and ill-made—is always being formed in greater or less quantity in every mouth in which absolute cleanliness does not exist. In the term absolute cleanliness I include the absence of vitiated secretions such as accompany, in greater or less degree, every derangement of local or general health. Although the third predisposing cause to which I shall come presently takes an important part in determining the localisation of caries in some cases, this second cause should, with the first, which has been already discussed, account fully for the association of caries as an accompaniment or sequel to constitutional disease. As factors these causes vary infinitely in quantity in different individuals. It is not possible to find two individuals with teeth exactly alike in structure, and with organic defects occupying exactly similar situations. Add to this that vitiation of the oral secretions as a factor in the causation of caries is of constantly changing potency in the daily life of each individual, and we fully account for the variability in different cases of the time of onset, the point of attack, and the rate of progress of the disease, as well as for its frequent intermissions.

In combating this second cause of caries, the patient's general health must first be considered, recollecting that probably every lapse from a perfect standard will be accompanied by a proportionate vitiation of the secretions of the mouth. The question of general health is for the physician, not the dentist. But even with perfect health and perfect dental tissues caries may appear if organic débris be allowed to remain and decompose in contact with the teeth. The first thing, therefore, in every case is to ensure mechanical cleanliness by the use of tooth-brush and tooth-pick, which latter should be of quill or wood only. I direct that it be used at night to clear away remains of food from between the teeth, before they receive their final brushing. Where the teeth are crowded and are of delicate structure the use of floss silk passed between the teeth and rubbed to and fro supersedes the toothpick. Until lately I have been prescribing as a routine for healthy mouths a tooth powder containing two drachms of Castile soap, half an ounce of powdered orris, two drachms of borax, and two ounces of precipitated chalk. To this has been added a few drops of oil of cloves and of oil of lavender or attar of roses. It is, however, very rare indeed to meet an individual in whom perfect health is constant, and in whom one or other of the predisposing causes of caries does not exist. I have, therefore, latterly begun to urge my patients to use habitually a tooth powder composed of the solid ingredients named but containing instead of perfume, carbolic acid. I begin with a mixture, containing 1 in 40 of carbolic acid—that is, twelve drops to the ounce of powder—and I sometimes prescribe as much as 1 in 20. This, however, is too strong to be borne where the gums are tender. To disguise the flavour of the carbolic acid, I add eucalyptus oil, from ten to twenty drops to the ounce. I direct the mixture to be used freely—to be taken up on a wet tooth brush, and the mouth to be freely rinsed with water at intervals during the brushing. In fevers and other diseases in which the patient is either too feeble or too listless to clean his teeth for himself this should be done by an attendant. In all cases where great vitiation of the secretions is present, as in the dyscrasia of pregnancy, extra means should be adopted to prevent putrefaction and fermentation in the deposits which form upon the teeth. Pasteur has shown that perchloride of mercury is by far the most potent drug we possess for this purpose; and a solution of a strength of 1 in 5000 is antiseptically equivalent to an 2 per cent carbolic acid solution, which latter, although not more powerful than needed to prevent fermentation, is too strong to be used as a mouth wash. I find a pleasant mixture of perchloride can be made if one grain be dissolved in an ounce of eau de Cologne or tincture of lemons. A grain of chloride of ammonium must be added to each ounce to prevent the perchloride from decomposing. Of this mixture a teaspoonful is to be mixed with two-thirds of a wineglassful of water, and the mouth to be thoroughly rinsed with it several times a day. Before leaving this subject, I must point out that without due exercise in mastication teeth cannot easily be kept clean; and where the function is impeded by the presence of tender teeth these must be brought into a healthy state or extracted.

The third main predisposing cause of caries is crowding and irregularity of the teeth. This favours retention of particles of food and of other organic débris for long periods in contact with the teeth; it also greatly prevents the constant beneficial rubbing and polishing of which, in a well-formed jaw, every tooth during mastication gets a full share, as well as impeding access of the alkaline saliva to those very surfaces where acid-forming substances find their location. This cause of caries mostly arises from smallness and malformation of the maxillæ, a condition which is, no doubt, largely associated with the physical type presented by highly civilised man. Of the causes of deterioration of the apparatus of mastication, I have not mentioned one which, in my opinion, is not without importance—namely, sexual selection. The type of female beauty for many ages has included a small delicate jaw. I am afraid we cannot hope that, for the sake of the teeth of posterity, men will be advised to pick out big-jawed wives, but we can at least seriously impress hygienists with the fact that the human jaw, for its due development, needs adequate use, and that no dietary, however otherwise suitable its constituents, can be perfect which is composed of uniformally bland and soft substances calling for little or no mastication. In the meanwhile we have to deal with the crowded jaws which daily present themselves. The most universally beneficial measure to prevent caries in these cases, especially where the teeth are of imperfect formation, is the extraction of the six-year-old molars as soon as the second molars are well in place. The first permanent molars are, with rare exceptions, the worst made teeth of the set, and in the cases where room is urgently needed, it is seldom indeed that their permanent preservation is possible. I am firmly convinced that the removal of these teeth at the epoch named is more beneficial than that of any others in causing an equal and sufficient spreading apart of all the teeth and preventing the evils of crowding. The operation of filing and polishing the contiguous surfaces of incisors and canines as a most effectual means of cutting short the progress of incipient caries in crowded jaws is too well recognised to need comment.

The regulating of teeth by means of mechanical apparatus may be of service in overcoming the cause of caries under discussion, but in the use of apparatus we must be on our guard lest we excite the very mischief which we desire to prevent. Regulating plates should not be allowed to chafe the teeth; above all, they should never be allowed to remain in place for more than a few hours at a time; they should be removed at frequent intervals and thoroughly purified; whilst with equal frequency the teeth should be well brushed with an antiseptic tooth powder, and thoroughly cleansed from the coating of food débris which is invariably retained upon their surface by the plates.

ON SOME ORGANISMS IN INDIAN CHOLERA STOOLS.



BY H. VANDYKE CARTER, M.D. LOND.,
BRIGADE SURGEON, H.M. BOMBAY ARMY.

UNDER ordinary circumstances I should have waited for the full report of the late German Cholera Commission before publishing the results of some inquiries of my own; but the appearance of a leading article by "E. K." (initials well known) in *Nature* of July 10th induces me now to state that in May last I communicated to the Medical and Physical Society of Bombay a provisional account, with preparations and drawings, of an organism I had found corresponding in aspect to Dr. Koch's cholera bacillus, as shortly described in the sixth Indian report of the said Commission. It is on the Society's records and upon the original drawing (see accompanying diagram) that the organism in question was compared by me to a vibrio rather than a bacillus; supposing that the delineations (as carefully done as possible) pertain to a single form, as they seemed to do. Latterly, however, not always meeting with the vibrio in cholera stools a few hours kept, and finding occasionally, though rarely, a similar organism in diarrhœal and dysenteric evacuations, I began to doubt the validity of my provisional identification, which has further been disallowed by an accepted authority in Calcutta whose valued opinion was sought. There being

Digitized by Google

as yet little that is peculiar told us regarding its cultivation, chemical, vital, anatomical and pathological relations, distant observers have to rely for guidance chiefly upon the morphological characters of the newly described cholera bacillus; and, unfortunately, I have not been able in India to see an authentic specimen of this organism. It is, therefore, the more remarkable that "E. K.," who in Europe has enjoyed such advantage, not the less arrives at results not much differing (as I judge) from those attained both previously and independently in Western India. Here, at least, is a noteworthy concordance. But in his identification, "E K." ventures further when asserting that "particularly a vibrio rugula"[1] is the organism which Dr. Koch describes as a

Organisms in Alvine Dejecta (Indian Cholera).

The so-called Cholera Bacillus (?), Vibrio (?), stained with roseine.
Fig. 1.—From fresh rice-water-like stools of a case which recovered; patient a low-caste man and a foul feeder probably. *a*, Common forms seen. *b*, Less frequent forms, and resembling vibriones more. A few ordinary putrefactive bacteria are shown, which will serve for purposes of comparison. × 800 : $\frac{1}{12}$ in., oil immersion.
Fig. 2—From a case of cholera supervening on variola (late stage) which proved fatal; material also fresh. *a b c*, Forms seen upon successive days, after which the stools became thicker and deep-coloured. × 650 : $\frac{1}{10}$ in., water immersion.

'comma-shaped' bacillus;" and if he be right, it well-nigh inevitably follows that the real cholera germ (if such truly exist) has still to be found. Because, first, it is *a priori* irrational to suppose that an everywhere widely distributed organism like vibrio rugula can alone be the essential cause of Asiatic cholera; and next, it is most improbable that mere imagination could have dominated the judgment of Dr. Koch. Doubtless the inference intended in *Nature* is that the so-called cholera bacillus is a myth; and be this as it may, some further details of the great discovery, declared to be assured, are now more than ever needed, especially by deeply interested inquirers in India.

NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.—At the meeting of this Association, which is to be held in Birmingham from the 17th to the 24th inst., the following special questions will be discussed in the Health Department, of which Dr. Norman Chevers is president:—The best method of dealing with town sewage, the products of house and street scavenging, and the products of combustion; the best means of securing those improvements in the dwellings of the poor which are essential to the welfare of the community; and how far the average death-rate of a population may be considered an efficient test of its sanitary condition. The hon. secretaries of this department are Mr. H. H. Collins and Dr. E. Seaton; and the hon. local secretaries, Messrs. G. A. Panton and R. M. Simon.

REMARKS ON THE

TREATMENT OF SYPHILIS BY HYPODERMIC INJECTIONS OF CORROSIVE SUBLIMATE.[1]

BY JOHN V. SHOEMAKER, A.M., M.D.,
LECTURER ON DERMATOLOGY AT JEFFERSON MEDICAL COLLEGE, AND INSTRUCTOR THEREON IN THE POST-GRADUATE COURSE OF THAT INSTITUTION; PHYSICIAN TO THE PHILADELPHIA HOSPITAL FOR DISEASES OF THE SKIN, ETC.

THE hypodermic injection of mercuric chloride for the treatment of syphilis has been received with great caution in the United States of America, notwithstanding that Dr. Lewin's book on the subject has been there translated and republished. I was one of the first to take up that treatment; and, encouraged by my success with it, read a paper on the subject before the meeting of the American Medical Association at St. Paul, Minnesota, in 1882. I analysed a number of cases treated in this manner by myself at the Philadelphia Hospital for Skin Diseases. I have since then practised it freely, and with even greater success than before. Syphiloderma of all descriptions were made to yield under this treatment, and no disadvantages of any consequence were experienced in its course. I have also tried the various additions and modifications of the original Lewin's mercuric bichloride injections. I have invariably given them up, preferring the method suggested by Lewin, in using a simple watery solution of corrosive sublimate. I have found, however, that the treatment could be carried very much further, and larger doses readily borne, and necessary for a thorough cure, than pointed out by him. I have invariably carried daily increased injections to the point where they produced systemic effect; and I have in many instances made, and found it necessary to make, injections of as much as half a grain (three centigrammes) per day. These strong injections were readily borne, providing they were sufficiently dilute, not less that half a drachm being employed for an injection containing half a grain (three centigrammes) of corrosive sublimate. When three large injections were reached daily, the systemic effect of mercury soon became apparent: as ptyalism, intestinal irritation, and occasional tremor, which, however, soon subsided on the cessation of the injections. Administration of potassium chlorate, and occasionally the exhibition of potassium iodide, although acting as an adjuvant in the treatment, did not serve to augment the systemic effect of the mercuric bichloride, but rather diminished its characteristic symptom. Stimulation by milk punch, and supporting treatment with ferrous iodide, were often found of great utility, but generally after twenty-four to thirty daily injections the syphilitic symptom had disappeared, and where the increasing dose had been persistently continued the relapse proved a rare exception indeed. I attribute the effect of this treatment to a formation of mercuric albuminate in the cellular tissue, which, insoluble to the liquids of the organism, gradually dissolved under the peptonising action found everywhere in the body, and thus produced a peptonised mercuric albuminate readily assimilable and eliminable in and through all parts of the body. I am led to this inference from the fact that otherwise toxic doses were innocent if injected under the skin; and if it were not for local irritation, I think even larger doses than I have mentioned could be borne without toxic effect. The local effects of the injection seem to bear out my views. Even large doses produce at most a swelling, which, though producing a somewhat erythematous condition of the skin, never suppurates or gives rise to deeper inflammation. I am free to say that in the thousands of injections I have so made I have never met with an abscess or serious inflammation, though the swelling of mercuric albuminate could be detected for several days. The only precaution I observe is to use a clean gold needle and to inject deep enough into the subcellular or connective tissue. Though the pain in these injections is always a disadvantage, if the solution is sufficiently diluted it will be lessened to a considerable degree, or augmented if more concentrated. No addition of any kind has in my hands lessened this, although I have with advantage ad-

[1] Read before the Section of Dermatology at the International Medical Congress at Copenhagen, August 12th, 1884.

Digitized by Google

ministered a quarter of a grain (a centigramme and a half) of morphine sulphate into the arm hypodermically prior to the injection of the corrosive sublimate. I regard it as necessary, to bring syphilis into abeyance and to obviate an early relapse, to constantly increase the strength of the mercuric chloride until its physiological effects are induced, and to continue its use in less vigorous manner until all symptoms have disappeared, sustaining the patient during this period with ailment, stimulant, and medication. Conducted in this manner, I regard the treatment of syphilis by hypodermic injections of corrosive sublimate as more rapid, reliable, cleanly, and less dangerous than either internal exhibition of mercurials, or iodides, or the combination of the two, or the filthy inunction treatment, either with or without variations. In no case have I found it necessary to use more than twenty to thirty injections, though I have frequently continued the after-treatment for a month or two, with decided doses of iodide of potassium.

LOBAR PNEUMONIA.

BY C. W. SUCKLING, M.D., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

DURING the past sixteen months I have had under my care, at the Birmingham Workhouse Infirmary, 100 cases of pneumonia. As this is one of the subjects inquired into by the Collective Investigation Committee, I think it my duty to publish the results of treatment and any facts especially noticeable in these cases.

Of the 100 cases, 73 were men and 27 women; 57 cases recovered and 43 died. The right lower lobe was affected in 40 cases, and the left in 33; the right upper lobe was affected in 17, and the left in 7. More than one lobe was affected in 3. The ages of the patients were as follows:—

Ages.	Cases.	Deaths.
Between 10 and 20 years	3	2
,, 20 ,, 30 ,,	13	1
,, 30 ,, 40 ,,	19	5
,, 40 ,, 50 ,,	17	5
,, 50 ,, 60 ,,	19	11
,, 60 ,, 70 ,,	18	11
,, 70 ,, 80 ,,	9	6
,, 80 ,, 90 ,,	2	2

It will be observed that the percentage of deaths increases with the age of the patient. The two deaths which occurred between the ages of ten and twenty years were cases of pneumonia of the upper lobe, one of which was complicated with acute Bright's disease, the pneumonia not being secondary to the kidney mischief, but both being due to the same cause—exposure to cold. In 24 cases the upper lobe was affected, and 10 of these cases were fatal; in 8 of these 10 fatal cases, there had been previous chronic bronchitis or apical mischief (phthisis). Uncomplicated apical pneumonia is in my experience no more fatal than ordinary pneumonia at the base; but where there has been previous lung mischief it is almost invariably fatal. Apical pneumonia was common in old age; 7 of the cases occurred in people of over fifty years. In 22 of the 100 cases previous lung mischief in the shape of bronchitis and emphysema existed. I find that where pneumonia supervenes in such cases it is very fatal. It will be observed that the majority (65) of my 100 cases occurred in patients over forty years of age, and there is no doubt that pneumonia in people over this age is greatly to be dreaded. It must also be remembered that the patients are derived from the lowest class of people—a class much addicted to alcoholism, and broken down by want of food and exposure, and therefore exceedingly bad subjects for an acute disease like pneumonia. There is a great contrast between these cases and those I have had as hospital patients; the latter as a rule do well, and we have little dread of pneumonia in a young and previously healthy subject.

Rapidity of onset, rusty expectoration, and critical defervescence were the three most constant symptoms in the above cases (in addition to the usual physical signs) Rusty-coloured expectoration occurred in thirty-five cases, and whenever this is present, I take it to be pathognomonic.

As regards temperature, I have only met with hyperpyrexia (a temperature of over 105° F.) in two cases, and both proved fatal. This may be accounted for by the ages of the patients, for I find that the older the patient the less the degree of pyrexia, and it is in young subjects that we meet with hyperpyrexia in pneumonia. Still, even in old people the temperature chart of pneumonia is characteristic, in that there is always a sudden rise and critical defervescence.

Cyanosis was observed in four cases only; all were over fifty years of age, all had suffered from bronchitis for years, and all proved fatal.

The pulse is the most valuable guide to prognosis in pneumonia. A pulse of over 120 in an adult is serious, and when over 130 the case is generally fatal. In twenty-two cases the pulse was noted to be irregular, and frequently intermittent, often becoming so as death approached. It is my custom to take pulse tracings in all severe cases, and I frequently find inequality in the base line, intermission, and irregularity in volume, often also hyperdicrotism. All such symptoms are to be regarded as very serious, and as a strong indication for the free use of stimulants. In fact, the great majority (I think I may say all) of cases of pneumonia die of heart failure.

Jaundice was observed in four cases, and the right lung was affected in all, the upper lobe in one, the lower in three. Herpes was observed in four cases. Diarrhœa occurred in five fatal cases; it was evidently not critical, for the temperature remained high; diarrhœa, unless critical, is a bad sign. Friction was heard over the inflamed lobe in ten cases. Hyperresonance (occasionally the cracked-pot sound) was frequently observed over the upper lobe when the lower was affected.

As to the cause of the attack, in one case only could I obtain any evidence of infection, and that was in the case of a woman who said, "I caught it from sleeping with my daughter, who has just had inflammation of the lungs." In many cases the disease was clearly attributable to exposure to cold; in several it came on after a bath. The majority of cases among patients previously living in the workhouse occurred during the winter months, when the weather was severe and easterly winds prevailed. It will be observed that nearly three times as many males as females were affected, the mortality being about the same in both.

In a disease like pneumonia, which is shortlived and in which there is such a great tendency to heart failure, a stimulant plan of treatment is in the majority of cases absolutely essential. I know that in children and young adults stimulants may be unnecessary. Aconite and tartar emetic may do good, but in the cases that I have had at the infirmary I dared not give them. In one or two cases where I have used these drugs, the patients being young and the fever high, dicrotism has become marked and delirium has supervened, necessitating the free use of stimulants. So that although it is by no means always necessary to begin with alcoholic stimulants, still I find that it is, as a rule, safest to put the patient on tonics and stimulant medicines—e.g., cinchona and ammonia. I am perfectly sure that I have saved several lives by free stimulation with alcohol; and were I to have pneumonia myself, I would prefer to be under the care of a physician who had no dislike to the use of alcohol in this disease. As to the treatment of hyperpyrexia, quinine is the best remedy, and perhaps the cold pack. I have used the cold bath once; but the effect on the pulse was so bad that I shall never use it again in pneumonia. To ease pain, morphia injections, hot poultices, or a few leeches suffice; I have several times seen good results from the use of the latter. Bloodletting in pneumonia, I believe, is rarely advisable, and in most cases is dangerous. In one case, where there was marked cyanosis, I bled to four or five ounces, with the result that the patient regained consciousness, but afterwards died. Perhaps if it had been done earlier it might have been more effectual. I have lately had four cases (occurring in the workhouse, and therefore seen on the day of the attack), in which the disease has been aborted by quinine in ten-grain doses. All these cases were characterised by rigor, rapid elevation of temperature to 104° or 105° F., and by the presence of fine crepitation. After the administration of a single ten-grain dose of quinine the temperature has immediately subsided, and the disease has not progressed, the fine crepitation disappearing in a day or two. For this knowledge I am indebted to Dr. Austin Flint, who says that pneumonia in its early stage may be aborted by quinine. In all cases seen early this mode of treatment ought to be tried. Where the lung will not resolve, I find the frequent application of iodine does good, or an occasional blister.

NOTES ON THE TREATMENT OF NIGHT SWEATS IN PHTHISIS.

By JOHN E. HOWE, M.B., M.R.C.S.,
LATE CLINICAL ASSISTANT AT THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

HAVING watched a number of phthisical patients during the last six months at the above hospital, I wish to state my experience of some of the drugs there used, and their power of alleviating this very common symptom—a symptom that it is very important to reduce as much as possible. These notes are from many cases, but especially seventeen cases on which daily reports were taken during their stay of many weeks in the hospital. These seventeen cases were under Dr. S. West, and I would here thank him for his kind assistance. The importance of nutrition in phthisis is admitted, and the fortnightly weighing-day is all-important for prognostic purposes, as without doubt night sweats favour wasting. Patients will have a better chance of improving their nutrition if this extra drain can be stopped; and surely night sweats and consequent damp clothes must add to the risks of fresh chills, besides making patients miserable and uncomfortable, and spoiling their night's rest. It is right, therefore, to prevent sweating if possible, although some physicians do not admit this, considering it useful in reducing the temperature; but that the hectic temperature is not due to the sweating is proved by the fact that the same character of temperature is maintained after the sweats have ceased under treatment, or even in some cases the temperature chart has markedly improved. It is well known what great power atropia has over night sweats, and it is the object of these notes to contrast with this drug some others used at Victoria-park Hospital—namely, strychnia, nitrate of pilocarpine, and oxide of zinc. Strychnia was first recommended by Dr. Lauder Brunton in the St. Bartholomew's Hospital Reports, 1879, from five to thirty minims of tincture of nux vomica having been given in four cases with success. At Victoria-park Hospital, from six to twelve minims of strychnia solution were prescribed as a night draught in many cases, and it succeeded admirably in most of them. The full dose of twelve minims was seldom necessary, but no ill effects or discomfort was noticed from so large a dose. Some of the patients slept very much better during the exhibition of the strychnia, to which gratifying result the increased comfort of the patient from absence of damp clothes may in some measure have conduced; but I think the drug had a good deal to do with the increased sleep, as this was not noticed in other cases in which the sweats were prevented by other drugs; in one case it markedly lessened the cough. Nitrate of pilocarpine was also given as a night draught, in doses varying from one-twentieth to one-eighth of a grain, one-twelfth of a grain being the most usual dose; in the majority of the large number of cases in which it was given the result was good, the patients being most grateful for the relief from the sweating. It seldom produced any of its physiological action, and, even if it did so, it was very slight sweating for half an hour after the draught, except in one case. One morning note only was as follows: "Sweated copiously for an hour after the draught;" but in this case, as in the others, there was no more sweating for the rest of the night. In a few cases in which the night sweats had commenced before the administration of the night draught, the sweating quickly terminated. Occasionally the action of the draught was not of long enough duration, for if given at 9 P.M. sweating would commence about 4 A.M. next morning. It is well in these cases to repeat the draught in the middle of the night. Oxide of zinc, in doses of from five to ten grains, was fairly successful in the few cases tried with it. In one case it was very successful indeed, as on discontinuing the drug the sweats recurred, to be again controlled by the same drug. It is necessary to state with regard to strychnia, and also pilocarpine, that their full action may not be developed the first night; also that the action of the drug lasts more than the one night, so that it is possible to discontinue the draught and yet no sweating occur for a few nights. In some cases even the habit of the sweat centre seemed permanently altered by the drug, and thus no more sweating occurred during the remainder of the patient's stay in the hospital. The result was not always so satisfactory, for in some cases the drug seemed to lose its effect, and the sweating previously prevented would slowly return, even during the continuance of the draught; but a change of drug was always successful in these cases. The three drugs, strychnia, atropia, and pilocarpine, only failed completely in one case—a man with phthisis, with his left pleural cavity nearly full of pus. Thus we see that strychnia and pilocarpine can influence night-sweats. But are they better than atropia? No, not better. Are they as good? Probably yes. They are nearly as sure, and they are free from the great drawback to atropia—viz., the dryness of the throat produced, which is very troublesome in some cases, and certainly appears to increase the cough. Some patients seem very subject to this dryness of the throat, and it is in these cases that it is so useful to have other drugs to fall back upon. It is wise to prescribe the atropia in a fluid form, as the pill may not be digested by the stomach. Thus in one case atropia pill ($\frac{1}{100}$ gr.) had no effect, whilst two minims of the atropia solution ($\frac{1}{100}$ gr.) was very successful. Also atropia and morphia had better not be combined, as their antagonism seems to prevent a good result; if the morphia is necessary, then prescribe another drug for the night sweats.

WEST LONDON HOSPITAL.

CASE OF TYPHOID FEVER WITH HIGH TEMPERATURE (105·8° F.) TREATED BY ICE PACKING; RECOVERY.

FOR the following notes we are indebted to Mr. Harold Hendley, house-surgeon.

Phœbe M——, aged eighteen, general servant, was admitted on May 22nd, at 5 P.M., complaining of having suffered for seven days from sickness, giddiness, and headache, but still able during that time to continue her work. She had slight dyspnœa, but no cough; lips parched, tongue moist and covered with a white creamy fur; skin hot and moist, face flushed, bowels open, passing frequent watery black stools; lungs and heart normal. The temperature on admission was 103·6° F.; at 7.30 P.M. the temperature rose to 104·6°; at 10 P.M. to 105·4°. She was then packed in ice for ten minutes. She expressed great relief. The temperature had fallen to 103·2°.

May 23rd.—Passed a fairly good night, delirious at times; at 9 P.M. the bowels had been opened seven times since admission; character of motion thin and yellowish. Temperature at 9.30 A.M. 104·2°; bowels opened five times; very restless towards evening. Temperature at 10.15 P.M. 105·2°. Again packed with ice for ten minutes. Greatly relieved. Temperature reduced to 102·2°.

24th.—Somewhat delirious during the night, and began to complain of aching pains all over the body, especially in the abdomen. Temperature at 9.20 A.M. 103·4°; at 6 P.M., 104°; at 10 P.M., 105·2°.

25th.—Abdomen very tender, especially in the right iliac region; four or five rose-coloured spots on the abdomen, disappearing on pressure. Temperature at 9 A.M. 104·4°; at 10 P.M., 105·2°.

26th.—Temperature at 9 A.M. 103·8°; at 10 P.M., 104·8°. Bowels open seven times.

27th.—Temperature at 9 A.M. 103°; at 10 P.M., 105·4°. Packed in ice for half an hour. Slight rigor. Temperature reduced to 103·2°.

31st.—Tongue still coated with white fur, but moist; lips parched; increased number of spots over the abdomen and thighs. The patient complained of a great deal of pain in the stomach, and hot fomentations with opium were applied. Temperature at 7.30 P.M. 102·2°.

On June 3rd and 4th a slight rise in temperature occurred,

Digitized by Google

5th.—Patient very irritable. Spots fewer, but larger and more raised. Temperature 102·4°. Diarrhœa still continues.

6th.—Temperature at 9 A.M. 101°. Patient more comfortable. Bowels open six times.

With the exception of a slight rise on the 8th, the temperature remained about one degree below normal in the morning, and one degree above in the evening until the 18th, when a relapse took place.

14th.—Took bread-and-butter; on the 15th still two or three spots on abdomen and chest, complains of deafness, bowels open once, motion thick.

18th.—Temperature at 9.30 A.M. 97°; 9.35 P.M., 103·4°; pulse weak and rapid, great pain in lumbar region. An enema was given at 10 P.M., consisting of castor oil and soap and water. Twenty drops of sedative solution of opium were given by mouth. Pains relieved at 11 P.M.; temperature 101·2°.

19th.—Pulse somewhat stronger, still rapid; bowels open twice, motion dark and watery. Temperature at 9 A.M. 101°; 2.30 P.M., 104·2°; 7.30 P.M., 101°.

20th.—Patient much better, but had rise of temperature in the evening.

24th.—Temperature still high, spots all disappeared, bowels opened twice; no pain in abdomen. Patient began to mend rapidly, though the temperature did not reach normal till July 7th. She was discharged July 22nd, fairly strong, temperature normal.

Remarks.—In this case the patient experienced great relief from each ice packing, and each time it was performed expressed great comfort both during and after the application. It seems to be much more efficacious than sponging or the wet packing; it is quicker than the former, and less troublesome to both nurse and patient than the latter. In this instance a waterproof was passed next to the bed with a blanket between it and the patient. A large quantity of ice was then packed next to the skin along the trunk only, and the mackintosh and blanket folded over. The patient experienced no shock from the ice, but seemed to like the contact. At the end of the packing, the ice being removed, the blanket was drawn over the body, the moisture absorbed and the mackintosh and blanket both withdrawn. The relapse in the case is difficult to account for, but the fact that the temperature came down at once after the use of an enema might lead one to suspect that it might be caused by the retention of effete matter in the bowel.

LEITH HOSPITAL.

CASE OF RHEUMATIC FEVER WITH HYPERPYREXIA (109·2° F.) FOLLOWING ACUTE TONSILLITIS; ICE PACK; TEMPORARY RELIEF; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. GARLAND.)

For the following notes we are indebted to Mr. Herbert C. Male, M.B., house-surgeon.

Margaret R——, a servant girl, aged twenty-four, was admitted about midday on May 23th, suffering from pain in the joints and pyrexia. She had been previously under treatment for acute tonsillitis, which had developed on May 13th, and for which quinine in three-grain doses had been prescribed. She had always been a healthy girl, but was of a nervous, excitable temperament, and had recently joined the Salvation Army. She recovered from the tonsillitis, but complained of pain in all her joints on the evening of May 24th, and was sent to the hospital on the following morning.

On admission she was flushed and feverish, complained of headache, pain in the knees, ankles, and hands, the ankles being considerably swollen; copious perspiration. Temperature 100·8°. She was placed between blankets, ordered a milk diet, and to be given fifteen grains of salicylate of soda with two grains of carbonate of ammonia in camphor-water every four hours. The affected joints were wrapped in cotton-wool. The evening temperature was 103°. She passed a very restless night, did not sleep at all, and complained much of thirst.

May 26th.—The pain in the joints much relieved. Temperature (8 A.M.) 102°. The patient was seen about noon by Dr. Garland and by Dr. Struthers, who had previously attended her. She was cheerful, but appeared to be very nervous. Respiration was noticed to be rather rapid, and she complained of some shortness of breath and of a sensation of "ringing in the ears." There was a faint systolic murmur in the mitral area. No evidence of pericarditis, and the pulmonary sounds were healthy. About 2 P.M. she complained of severe headache, but fell asleep shortly after, and slept till between 3 and 4 P.M., when she woke up suddenly in a great fright and said she had had a dreadful dream. She talked in a strange, excited manner, and attempted several times to leave her bed. About 5 P.M. the nurse thought the girl was "going off her head." She was restless and excited; answered questions correctly, but had a delusion she was going home. The pulse was rapid and the breathing accelerated. Temperature in axilla 106·2°; perspiring freely. She was given ten grains of quinine, and cold clothes were applied to the head, after which she was quiet and rested. At 6.45 P.M. she started up, talking in a loud, excited manner, imagining she saw things on the wall, and was with difficulty persuaded to lay down in the bed. Temperature 106.4°. Her head was ordered to be shaved, and her body sponged all over with cold water. About half an hour later she became wildly delirious, could not be reasoned with, and was so violent that she had to be strapped in bed. The thermometer rose to 106·6° in the axilla, but could not be properly retained, owing to her struggles. The clothes were now removed from the bed, and she was wrapped in sheets wrung out of iced water. She became much quieter, and soon lapsed into a semi-comatose condition. The sheets were changed frequently. At 8.15 P.M. the temperature had risen to 109° in the axilla. She was lying on her back with her mouth open, quite unconscious. Pulse rapid and feeble, respiration stertorous, pupils much contracted and insensible. One drachm of sulphuric ether was given hypodermically. 8.30 P.M.: Temperature in rectum 109·2°; pulse 140, barely perceptible; respiration irregular and gasping; death seemed imminent. Ice was packed over and round the body, in the axilla and hands, and half a drachm of ether injected. 9 P.M.: Temperature in rectum 106·6°; breathing freer. Still unconscious and insensible to stimuli. 9.15 P.M.: Temperature in rectum 103·6°; pulse 140, fuller; decided improvement in condition; pupils dilating and slightly sensible; feeble attempts to cough and occasional twitchings of hands. Half a drachm of ether injected. 9.30 P.M.: Temperature in rectum 100·6°; pulse 132; breathing much freer. Pinching the skin caused her to move slightly. She rolled her head from side to side, and tried to open her eyes. The cold pack was now removed. She was wiped dry, and placed on another bed between blankets. 10 P.M.: Temperature in rectum 98·4°; pulse 120, of fair volume; surface of body very cold. Hot bottles applied to sides and feet. Swallowed a little brandy-and-water with difficulty. 10·30 P.M.: Temperature in rectum 98°; pulse 112; respiration slower and less embarrassed. More sensible to external impressions. Pupils acting freely. No return of consciousness. Half-drachm of ether injected. 11.15 P.M.: Condition much the same. Twitching of muscles of mouth and attempts to expectorate. Moving about more in bed. 11.45 P.M.: She started as if suddenly awakened, uttering unearthly screams, expression indicating extreme terror. The slightest touch or approach of light produced general convulsive tremors and appeared to excite the greatest alarm. Temperature in rectum 101°; pulse could not be counted owing to spasms of hands when touched. Breathing laboured, long inspirations with peculiar hiccoughy catch at full inspiration. Saliva collected in mouth and spasmodic attempts of expulsion. Pupils dilated. Ice-bag applied to head, but had to be discontinued as it produced spasms. Ward was darkened, after which she was quieter.

27th.—12.15 A.M.: Temperature 102·4°; respiration 40. Lay quietly in bed, if left alone, with wild vacant stare, but screamed and shrank from anyone who approached or touched her. 1 A.M.: Temperature 104·8°; respiration 44, more laboured. A lighted candle produced violent convulsions and caused great agitation. Spasmodic contractions of muscles of mouth, with rolling of eyes and blinking; mouth firmly shut and attempts to spit saliva out of closed lips. Pupils widely dilated. The patient died somewhat suddenly at 1.20 A.M. with frothing at the mouth and symptoms of asphyxia. Temperature immediately after death 105·4°, and fifteen minutes after death 104·2°.

Necropsy, eighteen hours after death.—Post-mortem lividity very slight; rigor mortis present only in lower extremities. Dura mater congested and about two ounces of blood-stained serum escaped on its incision. Brain substance firm, vessels of surface distended; on section white matter presented a mottled injected appearance, the points

Digitized by Google

vasculosa being more numerous than usual; the brain appeared otherwise normal. Heart soft and flabby; right auricle and pulmonary artery contained firm decolourised clots; valves healthy. Lungs congested. Spleen enlarged, very soft and friable, and tore on removal. Liver much enlarged, adherent to diaphragm; surface rough and some thickening of capsule in parts; section very soft and fatty. Kidneys much congested, otherwise normal. The bladder was empty.

Remarks by Mr. MALE.—This case is interesting in illustrating the relationship between tonsillitis and acute rheumatism, to which Dr. St. Clair Thomson recently drew attention in THE LANCET, May 24th, and in showing once more the efficiency of the cold pack treatment in reducing temperature. Like many of the cases published, the hyperpyrexia was preceded by an alleviation of the joint symptoms and by insomnia. The occurrence of hyperpyrexia within forty-eight hours of the commencement of the rheumatic fever is unusual, and the extreme reflex excitability, at the last approaching almost a hydrophobic condition, I have not found mentioned in other cases. Death apparently did not result from exhaustion, but from spasm of the muscles of respiration. Some observers have noticed an increase in the amount of urine passed previous to the rise of temperature. In this case no urine was passed for ten hours previous to death, and at the post-mortem examination the bladder was found empty. The question arises, Was the suppression of urine caused by the elevation of temperature, or was it a factor in its production? The fact that there was no return of consciousness after the reduction of the temperature, and the subsidence of other grave symptoms, show the necessity of having early recourse to the wet packing, and not waiting till such alterations have taken place in the brain from the excessive tissue change, as must so seriously interfere with its functions and materially lessen the patient's chances of recovery.

SOOREE CHARITABLE DISPENSERY.

A CASE OF CATHETER FEVER; DEATH.

(Under the care of Dr. G. C. ROY, Civil Surgeon.)

JOOGUL, aged about thirty-two, Hindoo, came to the dispensary on May 19th, with the following history of his case:—Eight years ago he had gonorrhœa, and he had passed water in small streams for the last five or six years. Until about a month ago he could urinate only in drops, and with great difficulty and straining. Micturition was frequent, some fifteen or sixteen times in twenty-four hours, and each act used to take him half an hour, and made his life miserable. His urine was said to be clear. In other respects he was healthy looking. Catheterism was attempted. There was a tight stricture in front of the membranous portion of the urethra, which barely permitted a No. 3 catheter (English) to pass. As there was some bleeding in the manipulation, no further attempt was made on that day, but the patient was dismissed with a dose of quinine and tincture of opium.

On the following day he attended the dispensary with fever, which had come on some time during the night. A saline diuretic mixture and tincture of Indian hemp gave relief, and the patient soon felt as well as ever. He could pass water in better streams, and he asked permission to go home and present himself after a few days. He remained well for two days, when he had a relapse of fever, but not without shivering. The fever was of a remittent type; but the patient being away from any medical advice, nothing was done for three days. On the fourth day he returned for treatment. His temperature was then about 103° in the morning; pulse 120; great thirst, burning of the body, and restlessness, and complete anorexia. The bowels were costive. There was no pain over the bladder or perineum, or any tenderness on rectal examination or thickening. In fact, very careful examination was made to detect any formation of pus. He complained of pain over the region of the right kidney, which was full and tender, without any distinct sense of fluctuation. His urine was turbid and milky, as if mixed with pus, and contained bits of soft tissues. A poultice was applied over the right loins, and a mixture of Indian hemp was given. This was changed afterwards to quinine, tincture of perchloride of iron, and tincture of henbane; brandy was also given. On the 1st of June the temperature became subnormal. The body was bedewed with cold clammy sweat. Costiveness gave place to diarrhœa. Thoracic rales indicated œdema of the lungs, and he sank on June 2nd, retaining consciousness to the last.

The non-Bacillar Nature of Abrus Poison. By C. J. H. WARDEN and L. A. WADDELL. Calcutta. 1884.

THIS little volume embodies the results of an inquiry into the existence of the so-called "bacillus of jequirity seeds," with observations on the nature of abrus poison, its chemical properties and physiological action. The practical application of the knowledge thus far acquired to the treatment of cases of abrus poisoning is also indicated. The opportune presence of Dr. Koch and the German Cholera Commissioners at the Medical College Hospital, Calcutta, enabled the authors to conduct the bacterial part of the research with a thoroughness which they could not otherwise have hoped to attain. It is a little unfortunate for the authors that the main principle for which they contend has been anticipated in England by two other independent workers—namely, Klein and Benson.

In the first chapter the question of the presence in the seeds of jequirity of specific bacteria or their spores is discussed. The intensity of the abrus ophthalmia is said to depend on the strength of the infusion and the frequency of its application, and this fact is held to be inconsistent with bacterial infusion, and to be an argument in favour of a chemical action. The mere presence of bacteria at the site of inflammation is not regarded as remarkable, for the infusion used by Sattler was unsterilised, and the albuminous constitution of the infusion was specially favourable for the growth of micro-organisms. In the third chapter the essential lesions of abrus poisoning are contrasted with the alleged bacterial lesions described by M. Cornil. The sixth chapter deals with and disproves the alleged immunity against further attack which attends the injection of a single small dose.

The second part of the work is chiefly concerned with the chemical nature of abrus poison, the activity of which is held to depend on a substance of proteid characters, which is named abrin. The physico-chemical properties and composition of this active principle, its place amongst the proteids, and its relations with vegetable albumen are likewise treated of. It has also been found that the albumen of the roots and stems of abrus precatorius is poisonous. This discovery is of very great practical importance, and should serve to banish from the Indian Pharmacopœia the roots of this plant, which are recommended as a substitute for those of glycyrrhiza glabra as a demulcent. The poison is, however, only active when directly introduced into the circulation. Abrin is said to bear in many respects a strong analogy to snake poison. Like it, it may be taken by the mouth with impunity. Heat lessens the activity of both poisons, but affects abrin much more powerfully. The toxic symptoms of these two poisons also exhibit a certain degree of similarity—general depression, drowsiness, fall of temperature and hæmorrhagic lesions. The marked differences, especially the convulsive phenomena, are considered to be accounted for by the more complex constitution of snake virus. A chapter is devoted to an account of the physiological effects of abrin on the blood, circulatory system, body temperature, nervous and other systems.

The last part of the text has to do with the management of cases of abrus poisoning. It appeared from experiments on chickens that dialysed iron given hypodermically at the seat of the abrus injection prolonged life.

We have recorded a sufficient outline of this excellent work to point out its careful and painstaking nature. The alliances of abrin with venom globulin might tempt to a hasty generalisation.

Thirty Years' Experience of a Medical Officer in the English Convict Service. By JOHN CAMPBELL, M.D., Staff Surgeon R.N. Pp. 180. London: Nelson and Sons. 1884.

THIS is a work deserving the attention of all who take an interest in the important but difficult question of the treatment of our criminal population. The author has given us the results of a long practical experience. After having served as medical officer in the navy for fourteen years—a training which must have been useful to him in his subsequent career—he was sent out as surgeon-superintendent of a convict ship to Tasmania, shortly before the abolition of the system of transportation to the Australian colonies. On his return he was appointed medical officer to Dartmoor Prison, from which he was transferred to the charge of the invalid hulks at Woolwich, and on the destruction of the *Defence* by fire in 1857 to the old prison at Lewes. In 1860, on the completion of the new invalid prison at Woking, he was sent there in charge of the invalid convicts. In 1875 a portion of the Woking Prison was set apart for the reception of lunatic criminals, as distinguished from criminal lunatics who are confined in the prison at Broadmoor; and Dr. Campbell remained in medical charge of the whole establishment till 1882, when he retired from the service. He therefore had long experience in the management of a most difficult class of prisoners—men who, from disease, were unequal to laborious employment, and whom it was necessary, owing to their physical condition, to exempt from punishments which would have been applicable to healthy prisoners. Dr. Campbell has not given any details of the health or of the death-rate of the prisoners at Woking, but he says: "As a proof of the healthfulness of the situation, it will suffice to state that there has been an entire exemption from epidemics; and with the exception of one case of typhoid fever, occurring in a prisoner who had been employed in cleaning a drain, all the complaints were of a catarrhal nature." The chapters on malingering and on the lunatic wing at Woking give a good idea of some of the difficulties experienced by medical officers of prisons, and of the responsibility involved in the efficient discharge of their duties. The chapter on the treatment of prisoners is interesting, and especially with reference to the effect of the separate system on their mental and bodily condition. In the preface, Dr. Campbell, with reference to the views of those who think that too much cannot be done for prisoners, justly remarks: "It is very desirable to bear in mind that in carrying out any system prompted by humanity everything approaching to mistaken sympathy with its objects should be avoided, as suggesting to their minds excuses for their misdeeds, and tempting them to look upon themselves as ill-used individuals. This is perhaps the most important matter on which I would insist."

OUR LIBRARY TABLE.

Experimental Chemistry for Junior Students. By J. EMERSON REYNOLDS, M.D., F.R.S., Vice-President of the Chemical Society of London, Professor of Chemistry in the University of Dublin. Part III.: Metals and Allied Bodies. London: Longmans. 1884.—Any student who works carefully through Professor Emerson Reynolds' three excellent little text-books, and accompanies his work with a little additional theoretical study, will gain a sound, intelligent, and practical knowledge of inorganic chemistry. Such a course is superior to all others, and affords the highest kind of scientific training. Unfortunately it is practically impossible for most students of medicine. It might be adopted, and doubtless is, in the advanced classes of public schools and colleges; but for the ordinary medical student, with his three months' summer course, it is out of the question. Professor Reynolds describes in the three volumes no less than 664 distinct experiments, all useful and all sufficiently explained, and the experiments are interspersed with much valuable information of a theoretical as well as of a practical kind.

The Law of Adulteration. By THOMAS HERBERT. London: Knight and Co.—The passing of the Sale of Food and Drugs Act, 1875, inaugurated a new era in connexion with the protection of the public against adulterated or mixed articles of food, &c.; and it may be regarded as the outcome of the revelations which resulted from the extensive inquiry which was carried on in THE LANCET, into the extent and character of the adulterations which were practised at that time. The improvements which have taken place are, in many respects, very marked. Evidence of competency is now required before an analyst's appointment receives official sanction; the duties of analysts are defined, and the various proceedings which are authorised to be taken as to adulterations have been fully set out. But since the Act was first passed legal decisions on obscure points have been given, and other difficulties have been found to arise. These have, to some extent, been met by the Amendment Act of 1879; but notwithstanding this, it is by no means easy to understand precisely how far legal decisions influence the action of both the authorities and the public. The present volume professes to clear up all these difficulties, and from the manner in which the task has been achieved we can hardly doubt that the writer has assumed a *nom de plume*, and that the work is to all intents and purposes an authoritative epitome of the state of the law of adulteration emanating from an official source. Every legal decision bearing on the subject is to be found recorded in it; copious extracts are given from all the important official reports and documents bearing on the Acts; and the information is so put together that, whether help in coping with adulteration is needed on the bench, in the laboratory, at a meeting of town councillors, in the shop, or in the private house, it will be found with the least possible difficulty, and in a form well suited to its intended purposes.

Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin. Herausgegeben von RUDOLF VIRCHOW. Band XCV., Heft 3. Berlin: G. Reimer. 1884.—This number contains the following articles: 1. On the Fate of Tissues implanted in the Organism, by Professor Zahn of Genf. 2. On a Case of Ulcus Rotundum Simplex Vaginæ, by the same. 3. Contribution to the Physiology and Pathology of the Blood, by the same. 4. Researches on the occurrence of Putrefactive Germs in the Blood of Healthy Animals, by the same. 5. On the Absorption, Formation, and Deposit of Fat in the Animal Body, by Dr. Munk of Berlin. 6. The Bacteria of Swine Plague, by Dr. Klein of London. 7. A further Historical Sketch on Cæsarean Section in the Talmud, by Dr. Rawitski of Czarnikow. 8. On the Chemical Composition of the Urine of Swine, by Dr. Salomon of Berlin. 9. On Trichinosis and on Actinomycosis in Swine, by R. Virchow.—Band XCVI., Heft 1, contains: 1. Research on the Cicatrisation of the Arterial Intima and Media after severance by Ligature, by Professor Zahn. 2. On a Case of Perforation of the Uterine Wall by a Placental Polypus, with consequent Retro-uterine Hæmatocele, by the same. 3. Note on the Physiological Relation of the Thyroid to the Spleen, by Dr. A. Tauber of Warsaw. 4. The Influence of Baths (Fresh Water and Carbonated) and of Muscular Action on the Circulation, and on the Treatment of Heart Disease by these three factors, by Dr. Jacob of Curdowa. 5. The Action of Phosphorus on the Fœtus, by J. M. Miura of Japan. 6. Microscopical Researches on some of the Vital Phenomena of the Blood, by Dr. Lavdowsky of St. Petersburg. 7. On Gartner's (Wolffian) Ducts in the Human Female, by C. Rieder of Basle. 8. On Thermoneurosis, by Dr. Scherschewsky of St. Petersburg. 8. Note on Actinomycosis, by Dr. Oscar Israel

Opium Smoking and Opium Eating. By GEORGE SHEARER, M.D. 1883.—The nucleus of the present treatise formed the subject of an essay by the author on "The Medical Means of Counteracting the Effects of Opium Smoking in China, with Suggestions as to the best Method of Conducting Opium Refuges." This essay was awarded a prize of £50 in 1881. Besides enjoying the advantage of actual hospital work among the Chinese, the author has consulted almost every available work which has yet appeared on the subject. The little book is a thoroughly popular production written somewhat in the sensational style. We have, nevertheless, no wish to condemn the book. As good wine needs no bush, so we may say that the dreadful consequences of opium eating and smoking need no colouring. Dr. Shearer believes that if the practice be vulgarised it will die out. By which is meant that if we can get the habitués to see that their habit is disgraceful, mean, and cowardly, they will renounce the practice. Education of the moral sense offers itself as perhaps the most hopeful means of combating the vice, but its chances of successful operation are small in face of the miseries of the surroundings of the lower classes of Chinamen.

The Cinchona Barks. By FRIEDRICH A. FLÜCKIGER, Ph. D. London: J. and A. Churchill. 1884. — Dr. Flückiger is well known in the chemical world, and his researches on the cinchona barks have marked a new epoch in the history of these valuable medicinal agents. The present book is a translation from the original German text, with some additional notes by F. B. Power, Ph.D. Eight lithographic plates and one woodcut serve to convey pictorially some idea of the different varieties of the cinchonas and their botanical structure. These lithographs are excellent representations. A separate section is occupied with a list of the more recent publications relating to the cinchonas and cinchona barks. The work treats of the botanical origin of cinchonas; of the most important species; of remisia, the most closely connected allies of the cinchonas; of their habitat; of cinchona culture; of the modes of collecting the barks; their appearance and anatomical structure; the contents of their tissue; the location of the alkaloids; varieties of cinchona bark; so-called spurious cinchona barks; cinchona cuprea; commercial statistics; chemical constituents of the cinchona barks; amount of alkaloids; quantitative estimation of the same; their manufacture; history of the cinchona barks to the year 1737; and their history to the present time. It will be seen that the work is not only exhaustive, but thoroughly interesting. We may refer to the fact that Dr. Flückiger is the possessor of the Howard Medal.

The Guild of Good Life. By B. W. RICHARDSON, M.D., F.R.S—This small volume professes to be a narrative of domestic health and economy, and is published under the direction of the Committee of General Literature and Education appointed by the Society for Promoting Christian Knowledge. When it is remembered what a vast amount of experience Dr. Richardson has had in the writing of popular works, the readiness and skill with which he has produced the present volume of instruction and amusement will not excite surprise. Universal cleanliness is the main theme of the narrative, and it need not be said that where this desirable condition prevails, providence, thrift, and prosperity will not be wanting.

Hints on the Health of the Senses. By MACNAUGHTON JONES, M.D. London: Longmans, Green, and Co. 1884.—The author's chief desire in writing this little book is to offer to the public, as far as possible free from technical language and in the simplest form, some useful suggestions for the preservation of the delicate organs of special sense. The little work [illegible] the purpose for which it is intended.

Charities Register and Digest. With an introduction by C. S. LOCH. Second Edition. London: Longmans, Green, and Co. 1884.—This volume, which is published under the auspices of the Charity Organisation Society, is a classified register of charities in or available for the metropolis, and a digest of information respecting the legal, voluntary, and other means for the prevention and relief of distress, and the improvement of the condition of the poor. The scope of the Register is larger than that usually aimed at in such works. This is mainly due to the introduction of information with regard to the various provident agencies, a knowledge of which is of the first importance to the charitable; and also to the attempt which has been made to give prominence to those large charities of the working classes which are habitually overlooked, but which are administered with a familiar acquaintance with the general circumstances of the recipients, and have a potency for good which may greatly exceed the more distant, though equally genuine, charities of other classes. No reference is made to the City parochial charities, as these are, in all but five parishes, to be re-organised in accordance with an Act passed in the past year. The lists of charities for the blind, deaf and dumb, reformatory and industrial schools, boarding-out committees, institutions for idiots and imbeciles, and convalescent homes, have been made as complete as possible, including institutions which are not metropolitan. By all concerned in the relief of distress this book will be found invaluable as a means of reference.

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

WE learn from this report, which is of a highly interesting character, that the average daily number of persons receiving relief in workhouses during the year was 49,236, being a decrease of 1333 as compared with the number so relieved in the preceding year; but there was an increase of 1549 in the average daily number of persons who received out-door relief during that period, the numbers being 60,384 and 58,835 respectively. During the year 55,076 persons were under treatment in the workhouses for various affections, including 6372 cases of fever or other contagious disease, with a mortality of 13,164. Whilst there has been an increase of 641 in the total number admitted sick to workhouses, there has been a decrease of 28,275 in the number admitted who were not sick, thus showing a net decrease of 27,634 in the total number admitted during the year. The number suffering from fever or other contagious diseases was less by 1300 than in the previous year, and the total number relieved in workhouses was less by 28,474. Last year 605,865 new cases were attended by dispensary medical officers, which included 186,938 visiting tickets, and 106,071 persons were vaccinated or revaccinated during the same period. Of the 12,405 deaths recorded in workhouses, 2661 were attributed to old age, 1005 to atrophy, 2027 to diseases of the lungs, 981 to consumption, and 583 to fever. There were only 11 deaths from small-pox, as contrasted with 76 in the previous year. During the past three years it is satisfactory to learn that there has been a considerable decrease in the number of fever cases attended by dispensary medical officers, and although last year the decrease was not so marked as in the two previous years, yet it amounted to 358. The total expenditure of poor-rates for all purposes—viz., poor relief, medical relief, burial grounds, registration of births, deaths, and marriages, sanitary measures, expenses under Superannuation Act, &c., was £1,326,963, being an increase in the total expenditure as compared with the preceding year of £70,660. The current sanitary expenditure for the year was £52,285, in comparison with £51,345 in the previous year.

KING'S COLLEGE HOSPITAL has received a donation of £100 from the Queen.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 6, 1884.

QUARANTINE measures have once more proved themselves powerless in preventing the extension of cholera, whether by land or by sea. That quarantine, if rigidly carried out, may under some circumstances be successful we have no wish to deny; but we do maintain that in its application to European and other civilised countries having commercial and other intercourse, it affords little or no chance of success, and that by reason both of its almost certain failure and of the restrictions and conditions under which it has to be maintained, its application does infinitely more harm than good. "A quarantine," wrote Mr. SIMON, in his eighth annual report, "which is ineffective, is a mere irrational derangement of commerce; and a quarantine, of the kind which ensures success, is more easily imagined than realised." Quarantine, to be effective, must exclude from entry into a country or a district all persons coming from the infected country or district, except after such a detention as will cover the period of incubation of the disease to be dealt with, and it must prevent all communication between inhabitants of the two localities concerned. This necessarily involves the stoppage of all commercial and trading relations between the localities, including the stoppage of supplies of food and other necessaries, and it also means a prohibition of all passenger traffic except after detention for quarantine purposes. The result is that large lazarets have to be established, and here the actually sick, those suffering from suspected sickness, and the healthy, are huddled together. The occurrence of a single case of actual cholera, or of suspected cholera, amongst the detained involves for all the repetition of the period of detention; and the conditions of aggregation and otherwise under which such detention is alone possible are found to favour the spread of disease rather than to check it. In short, the lazarets themselves tend to constitute centres of infection. Any amount of disguise and deceit is practised in mild cases of illness to avoid further detention, and so it happens that persons who would have done no harm had they been allowed to pass on from the first, have, after contracting such an affection as choleraic diarrhœa, succeeded in securing their freedom only to convey infection in their track. Indeed, the restrictions of quarantine are so burdensome and vexatious that the more rigidly they are carried out, the more are contraband practices, both as regards persons and goods, resorted to. Land quarantine, or the application of a sanitary cordon, failed for this reason when Toulon was first affected with cholera; it also failed when applied by Italy against France, the disease, notwithstanding all restrictions, making its way into the provinces bordering on the French frontier and then extending further into the kingdom; it has failed as regards individual towns and cities in Italy, for notwithstanding the employment of thousands of troops, cholera made its way easily out of Busca and Spezia. It has since spread from Alicante in Spain as far inland as Novelda. The anticipation of quarantine also suffices to frustrate its intended purpose, for the moment cholera is known to exist in a town the inhabitants, fearing that they will be hemmed in with the sick, are seized with panic, and fly away hither and thither by any route that is open. It was in this way that cholera spread from several centres in the south of France, and in a similar way it was carried a distance of many miles by the multitudes who fled from Spezia. Land quarantine, indeed, was, according to a resolution of the International Sanitary Conference held at Vienna in 1874, declared to be impossible of execution and useless in view of the numberless and ever-increasing methods of communication which everywhere exist, and it was hence rejected by the Conference, the Italian representative, amongst others, assenting to the rejection.

Quarantine by sea is more possible of execution, but to be successful the country resorting to it must make up its mind to all but complete isolation, for unless it does so its attempts at exclusion of persons and things from suspected places will almost certainly be met by other attempts, and these generally the more successful, to evade the restrictions imposed. An example of this has just occurred in the case of the importation of cholera from France into Spain. The first appearance of cholera in Spain was at Alicante, on its Mediterranean coast; and there seems but little doubt either that persons unable to take ship directly from France to Spain without undergoing a vexatious quarantine had first travelled to Algiers and had thence reshipped, or that the quarantine measures at Alicante have of themselves failed. And so it has come to pass that the two countries that have maintained the most rigid quarantine against France have both become seats of the cholera by importation along the lines of human traffic. It was because all this was foreseen that the Vienna Conference, whilst recommending the adoption of certain regulations for those countries which still insisted on maintaining quarantine, passed a resolution recommending, in its stead, the system of medical inspection which is maintained in this country.

Of all the advantages which the system of inspection has over quarantine none is so important as the state of preparedness which it begets. Countries and towns relying on quarantine make no provision against its failure, and hence, directly disease succeeds in evading the measures adopted panic ensues. The system of medical inspection involves the examination of all and the isolation of the sick, and hence measures of isolation are provided beforehand. So, also, the country generally, having discarded its trust in quarantine and sanitary cordons, seeks to do away with the conditions which would favour the extension of the disease should it make its way into their midst, and it thus secures not only a better means of defence against infection than could otherwise be attained, but at the same time substantial improvement in its general sanitary circumstances, with consequent saving of life, health, and means. It is as yet impossible to say whether cholera will this year succeed in making an entrance into this country or not, but it is most certain that by the adoption of the system of medical inspection and isolation, together with the measures of sanitary reform with which that system has been allied, we are better prepared to meet the disease than we ever should have been

Digitized by Google

had we not abandoned resort to measures of quarantine, backed by the false sense of security which they engender.

WE must confess to a great deal of sympathy with the preference which Lord RAYLEIGH professes for the study of Classics as the basis of a general education. There is, of course, much to be said in favour of the utilitarian view which regards with regret the expenditure of a large amount of mental energy in the pursuit of knowledge on what is not in itself "useful," or perhaps we ought to say marketable. No one pretends to believe, for example, that the qualification of being able to make good Latin verses is of high commercial value. It must be conceded that the youth with even a smattering of science is better provided, so far as information—a totally different thing from education—is concerned, than the most learned classical scholar can be considered to be, for the active business of life. It is as true now as ever, though in a different sense, that Latin and Greek are for scholars and pedants, if we look only to the subject matter of the study pursued. At the same time, it is, for us at least, a serious practical question, whether the mind, or may we say the brain, nursed on classics, is not, after all, a better brain than the best that can be developed by exclusive forcing in the scientific laboratory. To speak frankly, we regard with dismay the growing tendency to discard the older methods of training.

We will give up at once and for ever the plea that classical learning may be turned to practical account; let it be counted as a drug in the market and unsaleable; yet, we contend, no better or more healthy mode of brain-training has been found than that which consists in compelling the youthful mind to such an exercise of its budding powers and faculties as is indispensable in the construing of works in the classical languages, and to express modern thought in the languages of ancient Greece and Rome. We will even go further than this, and dare to affirm that nothing in the whole range of educating work and processes is more directly conducive to the development of a brain strong and well furnished for the scientific study and practice of medicine than the intelligent and diligent study of Comparative Grammar and Logic. The argument employed in disparagement of the ordinary amount of training in classics may be used with equal fairness against any practicable school-training in science. No amount of dabbling in science—a form of mental discipline wholly inadmissible, as we believe, in the case of "clever" boys—will give that solidity of mind-structure, that depth and force and clearness of mind-vision, and that faculty of rapid and precise judgment in dealing with facts and drawing inferences, which are to be gained by fairly honest and earnest labour in the departments of scholarship just mentioned. Neither will we beg the question or try to evade the consequences of the view we take; but assert that, so far from agreeing with those who are striving to eliminate classical languages and classical work from the curriculum of a general and preparatory education, we believe they are pursuing a policy as opposed to that which experience and common sense combine to support, as one which would altogether supersede the natural rearing of chicks by a universal adoption of the artificial incubator. Let advocates of the "advanced" doctrine that knowledge is only useful if it be *itself* of use, pause before they destroy what cannot be restored, lest in abandoning the very principle of a sound education they deprive it of its backbone.

The study of modern tongues cannot, however useful in itself, replace genuine work in the classics. There was a constructive power in the old method which the new wholly lacks. The very fact that a language is spoken by contemporaries renders its acquisition valueless as a process of mental culture. The student of Science who has not been properly grounded in the classics, in mathematics, and in logic is at the mercy of caprice; his judgments are hasty, his processes of mental work are unformulated, his conceptions of law and reason are not definitive, and he is liable to be blown about by every wind of doctrine because he has no solidity, and therefore no stability, in himself. These may appear to be old-world notions, but we are prepared to maintain them on grounds physiological and psychological. In our own profession each year brings new and rapidly changing types of men and manners to the front. The expert scientist is a creature of to-day, and admirable in his place; but no class or development of mind and character which has yet been produced by recent combinations of forces, educational and constructive, will, for a moment, compare with that of the scholarly physician of the last generation but one. If it were only possible to keep the old stock and to graft upon it the excellences of the new, there would be a result not simply surpassing what has gone before, but ensuring a vastly improved and improving type of mental development in that which is to come. Let us maintain the sound classical basis, and afterwards raise upon it those more luminous and brilliant qualities to which the modern scientist so much aspires.

IT is gratifying to know that the financial success of the Health Exhibition has already been such as to relieve its promoters of all anxiety on that score. We can never fully realise the amount of trouble and anxiety which has been incurred in such a cause as this by men whose personal leisure is most scanty. Their enjoyment would be not in favouring a show of the coarser apparatus of sanitation, but in the pursuit of those profound and delicate investigations out of which the highest results for the race and the highest fame for the investigator are to be attained. It would have been grievous indeed if an undertaking in which so many of our foremost men of science and so many leading men in our own profession have taken part had been a huge failure, involving debt, and illustrating only the indifference of the public to that which so greatly concerns them—their health. The financial success of the Health Exhibition happily clears the way for the greater question of what we may call its scientific success. By this we mean not only the projection into the future of the interest in health questions on the part of the public which it has excited, but the elevation of such questions to a higher level of scientific respect. The public must be more than ever impressed with the importance of health questions, and it cannot show its sense of this importance better than by demanding that the profits remaining after all the expenses of the Exhibition have been defrayed

Digitized by Google

shall, in part at least, be devoted to the support or the creation of such institutions as contemplate the most thorough investigation of the causes of epidemic disease, and the way in which they are propagated from person to person, from house to house, or from country to country. Critics can easily find fault with this Exhibition. They can say that if there were only visible in it something having reference to health it would really be very interesting; that it is only a great show, meant to draw the public and calculated to advertise the wares of enterprising tradesmen; and it must be admitted that the scale of the Exhibition, the crowds by which it is filled, and the entertainments by which they are attracted, give a little plausibility to such criticism. But their objections will be effectually refuted if one result of this show should be the creation of a fund for the establishment of such scientific investigations as are worthy of the country that rules India, and to which JENNER and PARKES belonged. Such investigations are already honoured by the executive of the Exhibition. The instruments and the methods of PASTEUR are fully exhibited in a prominent place, as we have already explained; and there is in a somewhat inaccessible elevation of the building a Biological Museum under the fitting auspices of Mr. WATSON CHEYNE, in which work of the right kind is being done. It is impossible, however, to think without some shame of the much greater honour that is set on such work in Germany and in France than in England, which is so much in advance of other countries as regards public and practical sanitation. It is monstrous to think that in measures for solving the great problem of cholera, for which we have such a special responsibility, we have allowed Germany to excel or to anticipate us. France has made PASTEUR a Senator for his efforts to solve the mystery of epidemic and epizootic disease, and, like Germany, gives public support to bacteriological laboratories and museums. We cannot doubt that one result of the Health Exhibition will be to quicken public intelligence and interest in this question. The most highly civilised nations of Europe, with their huge armies, are painfully at the mercy of bacteria, many of which are so minute that, as Dr. DALLINGER has just told the British Association, fifty millions of them, if laid in order, would only fill the one-hundredth part of a cubic inch. It is these agents that we have to consider; their natural history, their relation to fermentation and to disease; how they can be fostered and how destroyed—in air, water, soil, or food; how they can be rendered innocuous or converted into beneficial vaccine agents. No use of the surplus funds of the Health Exhibition, no result of the Exhibition itself, could be more satisfactory than this. The authorities of the Parkes Museum, who have done so much to promote the success of the Health Exhibition, cannot make a better use of their influence than to make such a representation, and it would be no unfitting reward to them to constitute them the trustees of an endowment for the investigation of all questions bearing on health, from the disposal of sewage to the study of those organisms which, to all seeming, cause those mighty diseases which depress and decimate nations. Another purpose to which part of the surplus funds might very happily be applied is the relief of the pecuniary embarrassment of the London Hospitals. As a means for restoring the health of the people, who have so greatly contributed to the success of the Exhibition, the hospitals are unrivalled. We trust that the Prince of WALES and his colleagues will take both the objects we have mentioned into their most favourable consideration.

THERE are few, if any, surgical appliances which are more universally employed than the many forms of drainage-tubes. CHASSAIGNAC'S original wire tubes have entirely passed away, but their red rubber substitutes or the decalcified birds' bones are to be found in nearly every surgeon's repertoire. However much practitioners differ upon the great question of the dressing of wounds, they seem all to be of one mind as to the value of drainage, and not a few are fond of attributing all the success of Sir JOSEPH LISTER'S scientific and admirable wound treatment to his care in providing for proper drainage. The extreme frequency with which tubes are placed in wounds and sinuses tends in some measure to obscure the special purposes for which they are adapted, and it may be useful, therefore, briefly to recall what it is drainage-tubes can do, and why and when they are useful, as it will enable us to guard against their misuse, which is nearly as common as their employment.

It is well known that one of the chief phenomena in the healing of wounds is the pouring out of serum; this commences as soon as all hæmorrhage is arrested, and continues for from twenty-four to forty-eight hours. We need not stay to consider the purpose or the mechanism of this flow, but it is at once obvious that it is a twofold source of danger in those cases where the surgeon is attempting to secure the primary union of the wound. It may accumulate, separate the surfaces to be united, excite "tension" and suppuration, or it may form a fluid favourable to the cultivation of septic organisms, and so lead to local or general blood-poisoning. The purpose of drainage under these circumstances is evident, and with moderate care it is most easily secured. Tubes of sufficient size should be so placed in the wound as to facilitate the escape of the effused serum, and any part where there is a tendency for it to accumulate or "bag" should be specially provided for.

But now arises a question to which but very little general attention has been given: When and how should these tubes be withdrawn? The correct answer clearly is that as soon as the serous effusion has subsided the function of drainage-tubes is at an end, and they should then be completely withdrawn. We believe we are right when we state that a very common practice is to remove the tubes gradually, shortening them day by day; and then the surgeon finds that, while the rest of the wound heals by first intention, the track of each drainage-tube heals by granulation, or forms a sinus which is more difficult to close up than all the rest of a large wound. There is no difficulty in determining when a drainage-tube has ceased to be of use in a recent wound, for it will appear dry, and dryness of a drain is a certain sign that it is of no further use. To shorten it gradually, or to leave it in the wound at all, is but to manufacture a sinus.

This, however, is but one use of drainage-tubes. They find frequent and most valuable employment in quite ot

Digitized by Google

circumstances, and the different conditions demand other management. For example, in a sinus with a pouched, tortuous, or irregular track, discharge is apt to collect behind some temporary barrier and prevent altogether the growth of granulations that would otherwise take place. If a drainage-tube is introduced into the bottom of that sinus, it guards against this and secures the exit of the discharge from all parts under the influence of gravity, or of the elastic pressure of the surrounding tissues. The surgeon's aim in such a case is to secure the gradual growth of granulations and cicatrisation of the wound from the bottom, and to prevent closure of the wound superficially, or at any intermediate place. A drainage-tube is of use therefore to provide a means of exit of discharge from the deepest part of the sinus, and to allow of the unhindered growth of granulations there, while at the same time it prevents the adhesion of the walls, or closure of the sinus at any intermediate place. It should therefore project almost to the bottom of the sinus, and as the granulations sprout up at the bottom it will require to be shortened. When used in such a case, it would be folly to remove the tube in one piece; but daily, or at longer intervals, it should be shortened to an extent commensurate with the closure of the sinus, until the wound is superficial and the tube can be dispensed with entirely. The skill and experience of the surgeon are well tested by this process of shortening the tube; for if not done fast enough the healing is delayed; while if done too fast, the whole purpose for which the tube is used may be defeated, and the surgeon find, to his dismay, that although he has gradually shortened his tube to *nil*, the sinus is as long as before. The amount and character of the discharge, and the appearance of the granulations lining the sinus, afford some indication of the rapidity with which healing may be assumed to be taking place, and the careful use of the probe will of course render valuable assistance. There are many practical details in the use of drainage-tubes which can only be learnt by practice and careful observation; but we have stated, we believe, the principles which should govern their use in all cases. Where, as in recent wounds, a great and temporary flood of fluid has to be carried out, drainage is only a temporary requisite, and as soon as the flood of serum is stayed the tube should be wholly removed. Where, on the other hand, the tube is used to keep open a sinuous track with flaccid walls, liable to collapse or be compressed, and so occasion retention of discharge in the deeper parts, the shortening of the tube must keep pace with the healing of the sinus. When tubes are used in abscesses, they first of all form an exit for a considerable collection of pus, but so soon as the cavity is empty, and its walls have collapsed, its condition approaches that of a sinus, and the tube must be dealt with accordingly.

Ridicule has in some quarters been thrown upon the very common use made of drainage-tubes, and it has been asked whether fluid will flow through a tube in opposition to the force of gravity. Without undertaking to defend all the uses of tubes, it is only fair to point out that a tube may be of signal service in draining a cavity and sinus apparently in opposition to the force of gravity. Nor is the reason far to seek. The rigidity of the tube being sufficient to maintain an open path for the pus or other fluid to escape, the elastic pressure of the surrounding tissues or the growth of granulations from the bottom of the cavity presses out the fluid. Without the tube, the walls of the sinus or aperture collapse or are compressed together, and additional resistance is afforded to the exit of the secretion of the wound. Absorbable drainage-tubes have not yet been largely used in this country, and their value appears to be limited to those cases in which the first dressing of a wound is not removed until cicatrisation is complete.

IN dealing with the subject of Metaplasia, at the Copenhagen Congress, Professor VIRCHOW must have awakened memories amongst his older hearers of the great service he rendered to science in the enunciation of his cellular pathology more than a generation ago. For although in detail the application of the doctrines he then formulated has with the lapse of time and the advance of knowledge been materially modified, the central facts of cell growth and cell nutrition still largely dominate pathology. In the lucid sketch which prefaced the main subject of his address, Professor VIRCHOW showed how the doctrine of humoral pathology and the large share assigned to an assumed plastic force operating on a blastema from the blood, a doctrine which was fully advanced by HUNTER, and to some extent maintained by ROKITANSKY, came to be modified by the cell theory of SCHWANN, and how the weak point in SCHWANN'S theory, that cells have a *de novo* origin, was overturned by VIRCHOW himself in his enunciation of the law "Omnis cellula e cellulâ." He pointed out that the formative process and the nutritive were not identical, as was assumed in the older view; but that the effect of nutrition was the preservation of cell life, that of formation the multiplication of cells, in which the original cell loses its individuality, and, as such, ceases to exist. The cell theory of nutrition implies the taking up by the cell of material needed for its sustenance, and the casting off by it of effete matter. In other words, it is cell metabolism. But there is also the plastic force, which on HUNTER'S view resided in the structureless lymph or blastema exuded from the blood, but which VIRCHOW transferred to the cell itself, a power exemplified in all processes of growth, and especially in the exaggerated condition of this, to which he gave the name of hyperplasia.

The subject of metaplasia is intimately connected with the processes of normal cell life. It implies a conversion in the properties of tissues, an apparent new production, but yet not affecting the permanence of the cells which are the seat of this conversion. This process is one which has many examples in tissue life, both under normal and morbid conditions. A striking instance is afforded in the process of ossification, where the osseous tissue is formed, not by direct conversion of embryonic cells, but by the metaplasia of a tissue which occupies an intermediate position between the embryonic tissue and the fully formed bone. Whether the ossification take place from cartilage or from membrane, the essential thing is a change in property and function of cells; and the same applies also to the formation of marrow, which goes to make up the whole bone as an organ. The production of marrow may occur in a bone by the latter yielding up its lime salts and the osseous becoming changed into the medullary corpuscles, with softening of the matrix. Thereby a bone may pass into the condition of osteoporosis, or by a

Digitized by Google

further change, into that of osteo-malacia. Another striking instance of metaplasia is to be seen in the frequent conversion of adipose tissue into mucous tissue—a change which may well be termed a *re*-version, since in fœtal life the fatty tissue is represented largely by mucous tissue. Such a change, seen in the fat of the spinal canal, epicardium, renal hilus, and elsewhere, is not a mere atrophy of the fat, but a real metaplasia, a change in constitution of the fat cells. It can be seen largely in many myxomata and lipomata that exhibit more or less of the gelatinous myxomatous change. COHNHEIM'S doctrine, which relegates all tumour growth to a persistence *in loco* of embryonic elements, retaining the power to develop at any period of life into the tissue for which they were primarily intended, is, in spite of its attractiveness as a generalisation, in VIRCHOW'S view, inadequate for the explanation of many forms of tumour that must take their origin in changes occurring late in life. The idea of metaplasia may be pushed still further, so as to embrace the question whether tissues of one type are capable of conversion into those of another. This is a question to which those who hold to the embryological view of tumour formation find it difficult to assent. They see that the embryo is laid down on definite lines, and that the mesoblastic cells retain their potencies *ab initio*, and can never be transformed into the cells or derivates from the other blastodermic layers. Hence, the sharp distinction between tumours of epithelial type and connective-tissue type; and the difficulties that are sometimes encountered in explaining the origin of a tumour composed of the one type of cells in the midst of tissue of the other type. By accepting the doctrine of metaplasia this Gordian knot would be severed; and Professor VIRCHOW, who throughout—e.g., in reference to cancer—has believed that epithelial formations may originate in connective tissue, does not hesitate to do this, nor to suggest furthermore a conversion of epithelial into connective elements. By a happy antithesis he referred in this connexion to the boundless metaplastic powers which many have assigned to the wandering leucocyte, some going so far as to assert that such cells take a part in the production of every new formation, and capable of conversion into any type of tissue.

The question, it must be confessed, is one which has far-reaching limits in pathology. Indeed, if metaplasia be admitted as possible, and the conversion of one form of tissue into a quite dissimilar form be accepted, much of the foundation of present day oncology will be undermined. At the same time the acceptance of VIRCHOW'S views would do much to explain many an instance apparently anomalous and out of harmony with what has been assumed to be the natural order of things. It may prove that we are too prone to regard the processes of nature as bounded by the rigid limits which we have created for them in our own minds; for it is as true in pathology as in other things, that we are more disposed to accept facts in harmony with our preconceived ideas than to subordinate our ideas to facts. Professor VIRCHOW in this address, thought by some to be dealing with a worn-out subject, shows us the dangers that beset us in thus limiting the operations of nature; and has supplied material for reflection and examination which may do much to revive that interest in cell life that is in danger of being displaced by the more attractive subjects which now engross the attention of the pathological world.

IN selecting as the subject of the Presidential Address in Biology, at the meeting of the British Association, the Phenomena of Pelagic and Deep-sea Life, Professor H. N. MOSELEY has, we think, exercised a wise discretion. An important section of the vast materials obtained during the voyage of the *Challenger* has been entrusted to him for identification, arrangement, and examination; and no one is better qualified, by the prolonged attention he has bestowed upon the problems opened up by this voyage, to express an opinion upon the results that have been obtained by it, or to give a general review of the rapid development of our knowledge in regard to ocean life. It is not many years ago that naturalists held animal life in the sea to be restricted to a littoral zone, at the outside from fifty to a hundred fathoms deep. Beyond that depth, it was held, there was total darkness and complete stagnation of water, whilst the pressure became enormous — conditions rendering life, or at least the existence of any of the higher forms of life, wholly impossible. The several expeditions, however, that have been fitted out by our own and foreign Governments have shown that the profound depths of the great oceans are not incompatible with the life of fishes, of holothurians, bright-coloured starfishes, and numerous mollusca, and that, induced probably by conditions of temperature, currents of water sweep along the bed of the sea, cold indeed, but still containing sufficient oxygen to enable aeration of the blood to be effected, and to maintain the various operations of life. From Mr. BUCHANAN'S results it appears that, contrary to what has hitherto been accepted, the presence of free carbonic acid gas in sea water is an exception. As in the blood, what carbon dioxide is present occurs chiefly as a bicarbonate, in general more or less incompletely saturated, and it is owing to this that, as Mr. JOHN MURRAY has shown, after certain depths have been reached pteropod shells are dissolved, and disappear from the sea bottom, and at certain further depths globigerina shells suffer the same fate. The amount of carbonic acid normally present throughout the ocean is not sufficient to be inimical to life, though here and there there are probably large bodies of water highly charged with carbonic acid, owing to the presence of active volcanoes in the ocean bed. In regard to the effects of pressure, M. RENARD has shown that yeast, after being exposed to a pressure of a thousand atmospheres, equal to a depth of 6500 fathoms of sea water, for an hour, when mixed with a solution of sugar, gave no signs of fermentation till about an hour had elapsed, and a mixture of yeast and sugar solution did not ferment at all while actually under a pressure of 600 atmospheres, equal to a depth of about 3900 fathoms.

"Algæ, seeds of phanerogamic plants, infusoria, and even mollusca and leeches, were found to be thrown into a sort of state of sleep or latency by exposure to similar pressures, recovering from this condition after a shorter or longer period of return to normal conditions. A fish without a swimming bladder, or one with the bladder emptied of air, may be submitted to a pressure of 100 atmospheres, equivalent to a depth of 650 fathoms, without injurious effect. At 200 atmospheres, equivalent to a depth of 1300 fathoms, it becomes torpid, but soon revives when the

Digitized by Google

pressure is removed. At 309 atmospheres, equivalent to a depth of about 2000 fathoms, the fish dies."

These experiments, Professor MOSELEY remarks, are of the highest interest, but of course they labour under the disadvantage that they can only be made on comparatively small quantities of water, so that the oxygen is quickly exhausted, and the fish has no time allowed it to become acclimatised.

"A question of the utmost moment, and one that has received a good deal of attention, is that as to the source of food of the deep-sea animals. Certainly, a large proportion of this food is derived from the life on the ocean surface. The débris of pelagic animals sinks slowly downwards, forming on its passage a sparsely scattered supply of food for any animals possibly living at intermediate depths, but becoming concentrated as it were on the bottom. The pelagic animals depend for their ultimate source of food, no doubt, largely on the various pelagic plants, the range of which in depth is limited by the penetration of sea-water by the sunlight, and probably to an important extent is dependent on the symbiotic combinations of radiolarians with zooxanthella. But a large part of their food supply is also constituted by animal and vegetable débris derived from the coasts, either directly from the littoral zone or by rivers and the action of the tides from terrestrial life..... In the deep sea the ordinary cycle of chemical changes of matter produced by life is incomplete, there being no plants to work up the decomposition products. These therefore, in the absence of any rapid change of the deep-sea waters, must accumulate there, and can only be turned to account when they reach the surface waters on the littoral regions. Many interesting results may be expected to be obtained when the histology of animals from great depths comes to be worked out, and especially that of the special sense organs. At present very little has been attempted in this direction, principally, no doubt, because deep-sea specimens are too precious to be used for the purpose."

Professor MOSELEY, however, describes the remarkable eyes of Ipnops Murrayii, which are curiously flattened out, and occupy the whole upper surface of the mouth.

We have no space to follow the Professor through his interesting speculation on the mode of development of the deep-sea from the littoral fauna, nor of the origin of terrestrial animals from the littoral fauna, of which, mainly on developmental grounds, he entertains no doubt; but we recommend the perusal of the address to our readers as presenting a very valuable *résumé* of a comparatively newly opened field of research from the hand of a master.

DR. BEYER recently read a paper before the Naval Medical Society of Washington, U.S., on the action of carbolic acid, atropia, and convallaria, as experimentally studied, on the heart of the terrapin and frog. With regard to carbolic acid opinions are still at variance as to whether the first action is stimulation of the heart and bloodvessels, thus increasing the blood-pressure, or whether its depressing and poisonous effects are produced at once. HOPPE-SEYLER obtained a rise in arterial pressure just before the convulsions came on, and also a rise in venous pressure, which was even more decided. SALKOWSKY noticed an increase in the rapidity of the blood flow in the capillaries of the frog's web, followed by a slowing of the flow. LABBÉ also observed an increase in the strength of the systole in the early stages of the poisoning, and a contraction of the vessels. On the other hand, RIEDIGER referred to a slowing of the circulation in the web of frogs under the influence of carbolic acid; and GIES found that the lowering in the blood-pressure and the decrease in the pulse-rate occurred almost simultaneously with the introduction of carbolic acid into the circulation, and that after a time the normal pressure and pulse-rate returned. It is well known, also, that the circulation survives the respiration in poisoning by carbolic acid. BEYER has concluded, first, that carbolic acid in small as well as large doses acts as a depressant on the heart from first to last, reducing its rate, its work done, and the blood-pressure; second, that the heart, as long as it is supplied with good oxygenated blood, will, up to a certain degree, show what almost amounts to an immunity from the poisonous effects of the drug; third, that any effects produced by carbolic acid other than depressant are due to other causes, probably to primary stimulation of the respiratory centre in the medulla oblongata. The antagonism existing between carbolic acid and atropia is shown, first, by the fact that after the heart has been carbolised, atropia increases its rate and also its work; second, by the more rapid recovery which takes place after carbolisation under atropinised blood than under normal blood. BEYER believes with H C. WOOD that atropia must have a very powerful stimulant action upon the intra-cardiac accelerator centres, because after the heart has been completely paralysed by carbolic acid and allowed to recover under atropia, the rate in some of the experiments showed an increase of from 31 to 42 beats per minute. As regards the experiments on the isolated heart of the tortoise and frog with convallaria, the probable conclusions to be drawn from them may be thus stated: It increases the rate and slightly also the work done; raises the intracardiac and aortic pressure; arrests both auricles and ventricle in systole when medium doses are used. Large doses arrest the heart at once. It probably acts directly on the muscular tissues of the heart, and has a decided cumulative action, acting more slowly than digitalis, and being more persistent in its influence. So far as the results of BEYER'S experiments allowed him to judge, convallaria is contra-indicated in advanced cases of heart disease in which the muscular structure has undergone alterations. Convallamarin should be used in preference to any other preparation; not more than one full medicinal dose should be given daily on account of the cumulative action of the drug. It will be perceived that in many of his conclusions BEYER differs from some observers who have preceded him in this particular field of research. The experimental studies were carried out at the Johns Hopkins University, under the supervision of Professor NEWELL MARTIN, and evidently at considerable cost of ingenuity and time.

WE are glad to observe that the Local Government Board maintain their objection to the reduction in the salary of Dr. Angus Mackintosh, which the Rural Sanitary Authority of Chesterfield resolved to carry out, and that they have informed the authority that unless the original salary is paid, repayment of one-half will not be allowed out of the Parliamentary grant.

WE understand that it is the intention of the Local Government Board to institute an inquiry into the cause of the extensive prevalence of diphtheria at Upton Pyne, Devonshire.

"Ne quid nimis."

CHOLERA IN ITALY: "LET ILL ALONE."

STRANGE and pitiful reports are in circulation respecting the epidemic of cholera in Italy. The ravages of the disease have been considerable, but the terror which they have inspired surpasses all reasonable limits. Its most astonishing evidence is the ignorant panic-fear with which the poorer classes regard the simplest realities of medical treatment. At Naples the schools were being disinfected. A cry was raised that the children, healthy children, were to be taken to the cholera hospital. Frantic mothers, without the least occasion, stormed the schools, assaulted and nearly killed the officials, and rescued their children, whom no danger threatened. At Busca the inhabitants refused medical aid and attacked the doctors, thinking that the latter were commissioned to poison them. It would be difficult to say what reason these poor people might give for their vehement opposition to the means devised for their cure. There does not seem to be here any question of the rigour of quarantine. Cholera is an intractable and often a very rapidly fatal disease. Cases of its most malignant form have appeared in Italy. Possibly, its own disastrous course and end have been attributed in such cases to remedies which have been used unsuccessfully, even though skillfully, to arrest it. If so, we have another instance of the frequently fallacious *post hoc propter hoc* view of events. A fair degree of inquiry, a little trouble taken in unravelling causes, with some belief in the good as well as the bad in mankind, are needed to bring the Italian populace and all others to just conclusions in such cases. The manly and sensible conduct of King Humbert and of some of the clergy in visiting and helping the sick is a good omen, and may be expected to beget in the people generally a kindred spirit of cool deliberation.

OMNE VIVUM EX VIVO.

ONE of the lectures at the meeting of the British Association at Montreal which attracted a large audience was that delivered by the Rev. Dr. Dallinger, who took for his subject the Lowliest and Smallest Forms of Life, as revealed by the microscope. The lecturer, however, did not content himself with a consideration of the structure and functions of the lowest micro-organisms, but made his address the occasion for a review of the question of spontaneous generation. The lowliest organisms lie on the very verge and margin of the vast area of what we know as living. They possess the essential properties of life, but in their most initial state. And their numberless billions springing every moment into existence wherever putrescence appeared, led to the question, How do they originate? Do they spring up *de novo* from the highest point on the area of the not-living which they touch? Are they, in short, the direct product of some yet unrecognised force in nature, changing the dead, the unorganised, the not-living into definite forms of life? Having thus stated the problem, Dr. Dallinger again reviewed the experiments of Tyndall, Bastian, and others. As is well known, Bastian regards vital phenomena as inherent properties of the material called protoplasm, just as magnetism is the appanage of a magnet; so that if a chemist were able exactly to imitate protoplasm by combining the various ingredients in due proportion, and under necessary conditions, the resulting mass would exhibit all the essential phemonena of life. Carried to its logical conclusion, the argument of the supporters of archebiosis amounts to this: That life can be created out of inanimate forces. The champion of spontaneous generation would say: "I can manufacture uric acid out of less complex materials; the properties of substances depend on their molecular structure and condition. Why should I not be able to make protoplasm?" He recognises no hard-and-fast line between the living and the not-living, the organic and the inorganic. The corrosive action of hydric chloride, the explosiveness of gunpowder, are merely functions of the substances bearing these names; life is a function of the substance called protoplasm. "You can manufacture gunpowder, why not protoplasm?" These are the thoughts which agitate the minds of men like Bastian and others. However, it is not by thought, but by actual experience or experiment, that such important questions are to be solved, and the majority of scientists have decided that when experiments are carried out with requisite skill, as appears to have been done by Tyndall, no life appears in sterilised flasks containing dead matter. The law is as ever: only the living can give rise to the living.

THERMIC DYSPNŒA.

THE mode of action of heat in increasing the frequency of respiration has received different explanations at the hands of various authors. Ackermann, Goldstein, and others have explained the respiratory acceleration as due to warming of the central nervous system. M. Sihler has supported the doctrine of a reflex action, the afferent surface being the peripheral cutaneous nerves. M. Ch. Richet has recently communicated the principal conclusions at which he has arrived to the Académie des Sciences. When a dog has been tetanised by repeated strong electrical shocks, the temperature of the animal is elevated and the rate of respiration is increased. As soon as the temperature has passed beyond 40·5°C. (104·9° F.), the respiratory rhythm is accelerated to 200, 300, or even 340 respirations per minute. From this experiment Richet concludes that thermic dyspnœa may be of central origin and due to the heating of the blood and nervous system. But Richet also believes in a reflex thermic dyspnœa, as he appears to prove by placing dogs in a warm stove, the temperature of the internal viscera remaining normal when the atmosphere of the stove is 38°, the respiratory rhythm being raised to 300 or more per minute. This reflex thermic dyspnœa is not observed in man, in whom the skin is more fitted for transpiration. Richet has found that a muzzled dog soon became feverish when placed in a warm stove—e.g., the stove at 39°, the temperature of the dog became 42° in an hour. Even tracheotomy and the use of a cannula in a muzzled dog did not prevent the onset of a marked pyrexia, and the animal died asphyxiated; hence normal respiratory movements are insufficient to support life when a dog is placed in a hot medium. Chloral in an anæsthetic dose, abolishing all the reflexes, does away also with reflex thermic dyspnœa; the chloralised dog placed in the hot chamber, being unable to breathe faster, becomes overheated and dies. Morphia, even in large doses, does not prevent the respiratory acceleration. In order that the inspirations may be increased in frequency, it is necessary that the trachea be largely opened, so that there is no resistance to free inspiration and expiration, whereby the tension of carbonic acid in the lungs may be reduced. If the surcharge of carbon dioxide be too great, respiration becomes deep and slow. Then there is an asphyxial dyspnœa characterised by slow and deep inspirations, whilst the thermic dyspnœa is marked by rapid and superficial inspirations. Though chloral gets rid of the reflex thermic respiratory acceleration, it is powerless over the thermic dyspnœa of central origin. No reflex excitation seems to be able to prevent the occurrence of the central form of dyspnœa, whilst the reflex form appears to be under the control of the will, and of all peripheral stimulations—e.g., cold water affusion. The central form is said to persist, even after the temperature has returned to the normal; the

Digitized by Google

respiratory centre in the medulla not having lost its newly acquired rhythm, though cold water applications are then able to restore the natural rhythm.

STRANGE VIEWS OF A CORONER ON UNNECESSARY INQUESTS.

WE hope that the attention of the Registrar-General has been called to the peculiar views of Mr. Carter, Coroner for East Surrey, on the course to be pursued when children die without medical attendance. The subject of the inquest was a child aged two months, which had wasted away to a shadow. The coroner spoke in terms of blame to his officer, and asked what occasion was there for holding an inquest. The officer, Mr. Wells, replied that the deceased had not been medically treated, and the registrar for the district refused under the circumstances to register the death. The coroner remarked that it was a great shame the county should be put to such an expense in holding unnecessary inquests. If the registrar refused to register such deaths, it was the duty of the officer to report the same to the presiding magistrate at the nearest police-court in the district, and he would make an order compelling the registration. The officer replied that he could not compel the registrar to do that which he refused to do, and the matter dropped, a verdict of death from natural causes being returned. The coroner in this case seems grievously in the wrong. Can there be a more fit or useful case for an inquiry than one where a child is allowed to waste to a shadow without medical attention being called to it? Secondly, what is the coroner's ground for saying that when the registrar refuses, as in this case he most properly refused, to register a death, the duty of the officer was to apply to a police magistrate? We are astounded at such a doctrine, and at the attempt to throw on police magistrates, who have enough to do, one of the most obvious and urgent duties of coroners.

PUERPERAL SEPTICÆMIA.

THE previous workers in this field have been both numerous and celebrated, yet the question of the nature of the virulent agent of puerperal septicæmia has not been definitely settled. M. Arloing, whose name is well known in connexion with bacterial studies, has recently communicated a valuable paper to the Société des Sciences Médicales de Lyon, of which we propose to give a *résumé*. M. Arloing's attention was first given to the microscopical nature of the lochia, blood, and peritoneal serosity of women. Besides the epithelial elements and pus-globules in the lochia, punctiform micro-organisms were discovered, either isolated, arranged in pairs, or in short chains. Similar micrococci were seen in the false membranes and pus of the peritoneum in fatal cases. The blood contained a few similar organisms, but much more minute and difficult of investigation. Inoculations were performed with the purulent fluids into the peritoneum of rabbits, white rats, guinea-pigs, dogs, fowls, and ducks, but only the first-named animals succumbed. Rabbits have also died when the inoculation was made into the veins. Artificial cultivations of the puerperal virus have been made in a beef bouillon at a temperature of 35° C. in the open air, at normal pressure, as well as in an atmosphere of carbonic acid and *in vacuo*. Rabbits inoculated with cultures which had been raised to a temperature of 43° C. lived a much longer time than usual, and in some cases recovery even followed; where this was the case the animals were found to be protected against fresh inoculations. The following statements are worthy of consideration. If the rabbits were inoculated with very active virus cultivated *in vacuo*, they died with all the signs of septicæmia, but without suppuration. If the animals were full grown, and inoculated with the same agent cultivated in air, the disease progressed more slowly, and the lesions of fibrinous peritonitis were produced. Finally, if the virus were weakened by culture in an unfavourable medium, the disease evolved still more slowly, and suppurative inflammation of the serosæ took place. In all cases the same microbe was to be detected. The main conclusions arrived at were two in number: first, that the different forms of puerperal septicæmia are all due to the action of one living poison; secondly, that this micro-organism is unique, but has not been proved to be special to the puerperal state. It must be remembered that the puerperal period realises the conditions favourable to the introduction and evolution of the micrococcus in the human organism.

THE DRESS OF WOMEN AND CHILDREN.

DRESS is a thing more variable than the changes of season, which it is supposed to follow, and opinions upon it are infinitely more varied than its forms. With reference to this subject, taste has long existed as a mere sense not much affected on the whole by mental processes. Of late a change has come about; it has multiplied and strengthened its connexions with the intellect, and is giving forth judgments and laws of clothing founded on the teachings of physiology. An effort in this direction is embodied in a paper by Mr. Francis Vacher on the rational dress of women and children. It contains some serviceable hints as to the clothing of infants, particularly where it aims at shortening the inordinate length of skirt in which their lower limbs are usually entangled. The use of woollen underclothing at this and all ages is another point which receives a just recommendation. The author certainly enters on debatable ground when he insists that children at a later age should be warmly clad from neck to toes, with no part of the body exposed save the head and hands. He seems in this part of his paper to violate his own principle by carrying into active childhood the swaddling system which he condemned in infancy. There can be no valid objection to letting even young children go about with bare knees and forearms, as one commonly finds they do, provided that they have been accustomed to this degree of exposure from infancy, and have the rest of the body comfortably covered. With regard to the special dress of womanhood, Mr. Vacher has fairly earned the thanks of thoughtful members of the female sex by daring to substitute for the conventional corset a closely fitting under-jacket. The corset, with its stiffness and its "shapeliness," however it may be modified, is an untruth against nature, which can only be remedied by being done away with. An essential point is the distribution of the weight of clothes. Every physical necessity requires that this pressure should fall upon the arch of the shoulder or pelvic bones, and not, as we now find, upon a dress-girdle more or less tightly drawn round the middle of the body.

SMALL-POX AT THE CAPE.

ACCORDING to the *Port Elizabeth Telegraph*, the medical commission appointed to visit the lazaretto of the combined Mining Boards of Dutoitspan and Bultfontein has submitted its report to the Board of Health. The report states that twenty-nine bodies were found outside the building, eleven of them having been dead for three days, on all of which the characteristic small-pox eruption was apparent. The lazaretto consists of three separate wards. To the convalescent ward, the floor of which was as nature made it, there was no door, and the patients lay on the ground without mattresses, and with only one blanket each to cover them. In the other two wards the patients were much overcrowded, the floors were in a filthy condition, there was no chimney to allow the smoke to escape, and the sleeping arrangements were similar to those prevailing in the con-

Digitized by Google

valescent ward. No other food but flesh, bread, or porridge was given, and those patients who were unable to fetch the food from the doors, where it was deposited by the attendants, were compelled to do without. No medicine was, it is stated in the report, given. Two natives acted as nurses; the night-nurse, having during the night preceding the visit of the commission got drunk, left the doors open, and allowed several delirious patients to escape. In answer to an inquiry, it was stated that "the doctor never entered the wards, only looked in at the doors; his work was 'to skin the man'—i.e., to make post-mortem examinations." There was no fumigation or disinfection of clothes, and the thirty-seven convalescents discharged were actually allowed to depart in the very garments they had worn during their illness. There is no latrine system, consequently the excreta of those who were able to go outside was deposited within seven paces of the wards, and remained uncovered; those who were unable to walk or crawl outside had to, and actually did, relieve nature where they lay. In reply to the report of the medical commission, Dr. Wolff argues that, with the means at his disposal, he did all that could be done for the unfortunate patients, and denies that there was neglect or wrong treatment. To reconcile these statements is difficult.

SUICIDE IN THE LIVERPOOL WORKHOUSE ASYLUM.

A CASE of suicide has occurred in the Liverpool Workhouse Asylum. The unhappy man was a German captain, thirty-five years of age, who had attempted suicide before his admission by cutting his arms. At the inquest it was ascertained that he was generally a sober man, but that since his derangement he had taken to drink rum in large quantities. The workhouse attendant's evidence, reported in the *Liverpool Courier*, is as follows. He deposed that he received the deceased on Thursday night last. He was then told by the German vice-consul, who accompanied the deceased, that the latter had attempted to commit suicide by cutting his wrists. From what the vice-consul said, witness placed the patient in a room by himself. The man had some tea shortly after his admission, and at 10 o'clock the same night witness visited him, when he said he was all right. About eleven o'clock the next morning a doctor saw the deceased, who remained quiet until Saturday morning, when he became restless and wanted to go home. The doctor again visited him at 11 o'clock on Saturday morning; and as he a little later was very noisy and violent, witness reported it to the doctor, who ordered him to be secured in a padded room, which order was at once carried out. Witness as usual took him his tea at half-past four, but deceased would not eat anything, and only drank some tea. He saw the man again at 6 o'clock, and also at 10 o'clock, this being the last time when he saw him alive. At 5 o'clock on Sunday morning witness saw the deceased, dead. He had taken the bandages off his arms, tied them together, and then strangled himself. Richard Davies, an old man, who said he was the night attendant at the workhouse asylum, stated that he heard the deceased walking about in the padded room up to 12 o'clock on Saturday night, and as all then became quiet he concluded that the man had gone to sleep. At half-past four on the Sunday morning witness looked through the glass in the door of deceased's room, and saw a leg and a foot behind it. Upon opening the door he spoke to the deceased, but obtained no reply. On looking up he noticed the deceased's bandage over the corner of the door, and having cut the bandage he found the other end of it tied round the man's neck, who was in a sitting posture and quite dead. At the inquest the deputy coroner reflected on the medical treatment, and thought that more might have been done for the patient. The jury adopted this view, and expressed the opinion that there had been gross neglect on the part of the officials and of the doctors. The guardians have since had this verdict under their consideration, and have acquitted the medical men and other officials, and expressed the opinion that everything possible had been done. The occurrence of a suicide in a public institution is certainly unfortunate. It is the more open to criticism when, as in this case, the officials have been distinctly forewarned by a serious previous attempt. We certainly think that more effective vigilance should have been exercised by the attendants, and that on the night of admission the medical officer should have been summoned to see the case. It is monstrous, too, that an old man should be night attendant for such cases. We cannot share the opinion that the coroner seems to have expressed, that blisters and other medicines would have much availed to prevent the sad accident.

LONDON WATER-SUPPLY.

DURING 1883 Messrs. Crookes, Odling, and Tidy examined at the expense of the water companies 2224 samples of water collected by them from the mains and reservoirs of the seven London companies taking their supply from the Thames and the Lea. The proportion of samples free from recognisable ammonia amounted to 82·7 per cent. of the whole, the percentage in 1882 being 70·9, and in 1881 60·6. There has been also a successive gradual yearly diminution in the proportion of organic matter present in the Thames-derived water supplied to the metropolis, and this diminution is attributed by the examiners to the continuously increased efforts made by the water companies to improve their filtration and subsidence processes and arrangements. The quantity of nitrogen found ranged from about 0·150 to 0·225 of a grain per gallon, the quantity being on the average somewhat lower in the summer and autumn than in the winter and spring quarters. The quantity of chlorine amounted throughout the year to either close upon, or a little over, one grain per gallon, corresponding to about one and three quarters of a grain per gallon of common salt. As the examiners remark, it is satisfactory to note that at periods of summer heat and drought the natural agencies at work to keep down the proportion of organic matter existing in the water of the river are in their maximum of activity. It results in this way that the water-supply of London is at its best at those seasons of the year when any failure in the quality of the supply might be considered likely to be of exceptionally serious import.

PENNY DINNERS FOR SCHOOL-CHILDREN.

THE penny dinner movement is extending. Prosperous accounts are given of its establishment in Gateshead by the Rev. Mr. Ede. His statements make it clear that there is need for some such provision for ten to twenty per cent. of the Board School children whose parents cannot or will not themselves feed them regularly. Payment is, on the whole, punctual, and the scale on which the system is worked allows of a surplus sufficient to pay for cooking expenses after the first outlay on the purchase of apparatus, a very moderate sum, has been met. It is found that there need be no stint in order that every child may enjoy a dinner and have enough. In very necessitous and selected cases where even the penny cannot as a rule be paid, charity is resorted to. Under the circumstances this appears but natural, seeing that education is compulsory, and that unless food be sufficient its benefit must often be overbalanced by injury to health. The dietary, so far as it goes, leaves little to be desired, price being considered. It is framed in recognition of the value which fats and amyloids possess as foods,

Digitized by Google

especially in childhood. The share of meat proteids in nutrition is not, however, forgotten. Ox-head soup with bread and various substantial flour puddings may be quoted as examples. Many simple dishes could probably be contrived on the same plan as these. No doubt variety will come with experience. The success of this thrifty experiment in cookery is a matter for general congratulation, and shows how much can be done by the skilful combination of common-sense with a good purpose and very scanty means. The hint may be worth the attention of many of all ages and occupations who have now to pay well in order to fare badly.

CHOLERA MIXTURES OF THE GENERAL BOARD OF HEALTH.

SEVERAL inquiries have reached us as to the ingredients of a mixture which the General Board of Health recommended on Oct. 5th, 1848, as efficacious in dealing with the premonitory diarrhœa of cholera, and as generally applicable to looseness of the bowels during the prevalence of cholera. Two alternative mixtures were embodied in the circular which the Board issued at that date. One prescription recommended was "seventy grains of opiate confection, mixed with two tablespoonfuls of peppermint water, or with a little weak brandy-and-water, and repeated every three or four hours, or oftener, if the attack is severe, until the looseness of the bowels is stopped;" the other, "an ounce of the compound chalk mixture, with ten or fifteen grains of the aromatic confection, and from five to ten drops of laudanum, repeated in the same manner;" and it is added that "from half a drachm to a drachm of tincture of catechu may be added to this last if the attack is severe." It was further recommended that half these quantities should be given to young persons under fifteen, and still smaller doses to infants. But, perhaps, the safest portion of the recommendation issued by the General Board of Health was that in all cases, where this is practicable, even in the earliest stages of the disorder, recourse should be had to medical advice on the spot.

ALCOHOLIC DISEASE IN CHILDREN.

ONE of the most painfully interesting communications at the recent meeting of the British Medical Association was by Dr. T. M. Madden, Physician to the Hospital for Sick Children, Dublin, on Alcoholism in Childhood and Youth. Dr. Madden testified that many such cases came under his view. He gave particulars of a case of marked delirium tremens in a boy aged eight. His mother was a drunkard, and he, at the age of six, on discovering a secreted bottle of whisky, showed the hereditary tendency to follow her example. Before admission into the hospital with delirium tremens he had obtained access to a bottle of port wine and almost emptied it. He nearly died from coma, and, delirium tremens supervening, he was taken to the hospital. Boils followed, and he remained weak in mind and body for nearly a month. He was then sent to a reformatory, and recovered. A second case of juvenile alcoholism in a newsboy, aged eight, was the son of a drunken mother. He was sent for his mother's whisky, and was rewarded with a sip. Dr. Barlow of London followed with some powerful facts as to infantile alcoholism, gathered from his experience in the Children's Hospital, Ormond-street. He had seen the evil effects of small doses of gin given to babies at the breast for flatulence. He had also found it customary to give quite young children among the poorer classes a daily quantity of beer. He had seen two or three cases of well-marked typical cirrhosis, with a little ascites, from this cause. He detailed one very striking case —the child of an apparently healthy mother, able to suckle it, and in fair circumstances. From six months old the child was given a tablespoonful of beer twice daily, and from nine months old a teaspoonful of gin in as much water daily. The child died, and was found to have one of the most typically hob-nailed livers Dr. Barlow had seen. Dr. Barlow properly added that he had seen hob-nailed liver in children where it was not possible to have alcohol. Dr. B. O'Connor bore similar testimony. These are appalling facts, which give great force to the warning of Dr. Madden and Dr. Barlow as to the responsibility of prescribing alcohol to children.

THE LATE DR. BALFOUR OF BOMBAY.

SOME weeks ago it was our painful duty to chronicle the sudden death of this medical practitioner, which took place in Bombay. We have recently been favoured by Dr. R. Blaney of that city, who attended the case, with some particulars regarding the illness, from which we glean that Dr. Balfour had been ailing for some time past, and that, to use the words of our correspondent, "he seemed to have been suffering from symptoms of incipient general paralysis for some little time before his death." We also learn that, under the advice of another medical friend, he had been taking strychnine, and on the day on which the fatal apoplectic seizure supervened Dr. Balfour was very unwell, and confined to his bedroom. He never rallied from the attack. Dr. Blaney, having been called in at 1 A.M., stayed with his patient until he died, three hours after the arrival of the former. "The little I was able to do for him," he tells us, "was of no avail, as he was beyond human aid. His death was very sudden, and was a great shock to all his friends here."

CONFERENCE ON CHOLERA.

THE Epidemiological Society recently held a conference on Cholera at the International Health Exhibition. As was to be anticipated, the controversy elicited the most opposite opinions. Sir Joseph Fayrer and Dr. Lawson argued strongly in favour of the non-contagiousness of the disease, whilst Brigade-Surgeon Scriven brought all his force to bear against this view. Dr. Scriven was, however, no supporter of quarantine. Medical inspection, surveillance, disinfection of ships, and burning of infected clothing were the chief preventive measures advocated by him. Taking the whole mass of scientific men, Dr. Scriven thought "the anti-contagionists would be found to be a very small proportion; but in England and in India, if they were a small minority, they were a very influential and very active minority—active, not in the suppression of cholera, but in the propagation of their own views." Another opinion for which he contended was that sporadic cholera was of exactly the same nature as epidemic cholera, just as sporadic small-pox resembled the epidemic disease. *Nulla falsa doctrina est quæ non permisceat aliquid veritatis.*

CULPABLE CARELESSNESS.

AT Melbourne, on July 4th, a coroner's jury returned a verdict of manslaughter against Dr. Günst, jun., a homœopathic practitioner of that city, as the result of an inquiry into the death of a young woman whom he had professionally attended. The patient complained of pain in the ear, deafness and sleeplessness. For this latter Dr. Günst wrote a prescription ordering ten grains of hydrochlorate of morphia and five grains of quinine to be mixed in a powder and "to be used as directed." The chemist to whom the prescription was taken concluded from the strength of the dose of morphia and the fact that the powder was to be *used* as directed instead of to be *taken* as directed, that it was intended for external application. This, however, was not the case. The unfortunate young woman swallowed the entire powder, and death resulted in an hour. The explanation given

Digitized by Google

by Dr. Günst was that he intended to write a homœopathic prescription, and that he omitted to put in signs recognised in homœopathy which would totally alter the character of the powder. He omitted to place before the quantities of the drugs signs indicating one-twentieth, and the effect of this neglect was that the patient got twenty times as much morphia as he intended; in other words, the ten-grains placed opposite the morphia was designed to apply to a preparation containing one part of morphia to nineteen parts of sugar of milk. The jury returned a verdict to the effect that deceased had come to her death by taking an overdose of morphia prescribed by Dr. Charles Werner Günst, jun., against whom, as previously stated, they found a verdict of manslaughter. The luckless homœopath was committed for trial, being, however, admitted to bail.

THE BRAIN AND PHOSPHORIC ACID.

THE peculiar associations suggested to exist between mental action and the use of phosphorus have been a favourite theme with many physiological chemists. Recently M. Charcot communicated a work by M. Mairet to the Académie des Sciences. The latter gentleman believes that phosphoric acid is intimately associated with the nutrition and action of the brain. In working, the cerebrum is said to absorb sodic and potassic phosphates, and to give out phosphoric acid combined with an earthy base. Intellectual work is believed to retard the general nutrition. Mental exercise modifies the elimination of phosphoric acid by the urine; it diminishes the proportion of acid in combination with alkalies, and increases the earthy phosphates.

CASE OF REPORTED CHOLERA AT KILMACTHOMAS.

DR. BRODIE states, in a recent report to the Local Government Board for Ireland, that the death of the stowaway lately admitted into Kilmacthomas Union was not, in his opinion, an example of Asiatic cholera. On the other hand, Dr. Martin, of Portlaw, who has had large experience in the epidemics of 1832, 1834, and 1849, asserts most positively that Kennedy died from the disease in question. It is probable that Dr. Martin will shortly publish the particulars of the case.

AN IRISH VETERINARY COLLEGE.

DR. LYONS, M.P. for Dublin, who has taken considerable interest in the formation of a Veterinary College for Ireland, has again drawn attention to the subject. It appears that the Irish Executive wish to subordinate the proposed institution to the English College, while the most earnest promoters of the Irish College consider it an essential point that it should be independent and capable of conferring a diploma of its own.

CURE FOR SCIATICA.

A REMEDIAL agency not commonly resorted to has been recently brought under notice by M. Debove for the relief of neuralgic sciatica. This physician seems to have met with considerable success in the treatment of sciatica by freezing the skin. Richardson's ether spray not proving satisfactory, M. Debove employed the chloride of methyl, which may give rise to a degree of cold represented by −23° C. This agent has the advantage of not being expensive. A jet of the fluid is made to play on the skin along the whole length of the limb corresponding to the course of the sciatic nerve and its main branches. The good effects are said to be instantaneous. The operation is also claimed to be but little painful; the smarting is not so great as that caused by the hot iron. Vesication has followed the employment of this remedy, but never any sloughing. The extension of this measure to other neuralgiæ is advocated.

HOSPITAL SATURDAY.

IT is gratifying to see many indications of earnestness in the promoters of the Hospital Saturday Fund, and especially so to notice that the main and most important branch of the Fund—the weekly small contributions of working men—are receiving more attention. Not till the working classes realise how easy it is for them to give such contributions, and how much they owe to the hospitals, will the Fund be worthy of them or of the cause.

BRITISH residents and visitors at Geneva have addressed a requisition to the British Consul that a meeting may be called to protest against the statements made by certain newspaper correspondents as to the sanitary state of the city and the existence of Asiatic cholera therein.

DR. CHARLES, of the Bengal Army, has medical charge of the Afghan Frontier Commission.

SUTTON, in Cheshire, is suffering from what appears to be a severe outbreak of typhoid fever.

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

(*From our own Correspondent.*)

(Concluded from p. 384)

ON Thursday, the 14th ult., in the Section of Surgery, Professor Macewen read a paper on Osteotomy for Genu Valgum. Professor Ogston said that he had given up performing this operation in the way he himself had originally recommended, and now used Macewen's method. Professor Chiene stated that it was now adopted by nearly all surgeons, and congratulated Professor Macewen upon being the inventor of this valuable method of operating. On the same day the discussion on Antiseptic Treatment was opened by Professor Esmarch (Kiel), who recommended his "Danerverband," the advantage of which is that besides being aseptic it keeps the wound perfectly quiet. Professor Esmarch pointed out that it was necessary, before dressing the wound, to carefully stop the bleeding, to provide for free drainage of matter, to be cautious in the use of the antiseptic, to employ good absorbent dressings, and to keep the wounded part quiet. Professor von Mosetig Moorhof (Vienna) recommended iodoform strongly as an excellent dressing for all kinds of wounds. He had never seen any fatal case of poisoning, but would utter a warning against using other antiseptic means, especially carbolic acid. Dr. Schede (Hamburg) spoke highly of the treatment of wounds by sublimate, his experience being based upon a very large number of cases. He had first used carbolic acid, which for some time yielded good results, but as, later on, various circumstances, such as bad drainage, the neighbourhood of the dissecting room, &c., had proved unfavourable, he had been forced to abandon the antiseptic treatment with carbolic acid. He had then tried iodoform, but had had sad experience of its dangerous nature from the occurrence of erysipelas. Dr. Schede was astonished to hear that von Mosetig Moorhof had not as yet seen any fatal cases of poisoning, as that was quite contrary to other surgeons' experience. Since he had used sublimate he had met with great success. Dr. Mikulicz (Cracow) recommended iodoform gauze (30 to 50 per cent.) for wounds in cavities lined with mucous membrane. He did not powder the wounded surface with iodoform, but simply filled the whole cavity with iodoform gauze, never omitting the usual antiseptic precautions, and left the gauze *in situ* for from

Digitized by Google

six to ten days. The advantage of this dressing was that the gauze kept the wound quite antiseptic; even if saliva, urine, &c., passed through it, it produced no irritation whatever, and the discharge was slight and without fetor. He had only seen cases of poisoning where there were larger absorbent surfaces, but none of these had proved fatal. The discussion was continued by Professors Trélat (Paris), Neudörfer (Vienna), Buchanan (Edinburgh), the last recommending pure Listerism, and Kœberlé (Strasbourg), who spoke against all antiseptic treatment, considering that the principal point was cleanliness. Finally, the President, Professor Plum (Copenhagen), gave a summary of the development of the antiseptic treatment in Denmark, which was one of the countries where the Listerian treatment had first been adopted; lately the German modification had been much used. The President pointed out the great benefits Lister had conferred upon surgical science and upon mankind. The large assembly rose to testify their sympathy.

In the Hygienic Section, Dr. Dutrieux (Alexandria) read a paper on the Cause of Cholera in Damietta, a theme which gave rise to a lively discussion.

On the evening of the same day the municipality of Copenhagen gave a dinner in honour of the Medical Congress, at which fourteen hundred persons were present. As the town contains no hall sufficiently large to dine so many persons at once, a beautiful wooden building was erected for the occasion. Decorated with bunting, flowers, and evergreens, and situated between the charming "Lange Lime" and the blue waters of the Sound, the dining hall seemed worthy even of the distinguished guests it was to contain within its walls. The side towards the sea was almost entirely constructed of glass, so that the guests had a splendid view of the harbour, covered with ships from all nations, all decorated with flags in honour of the occasion. During the dinner large steamers passed within a few yards of the building with enthusiastic crowds on board, waving their welcome to the foreign guests. After dinner the party was conveyed in three steamers to the well-known gardens of Tivoli. This short voyage might be almost called a triumphal procession, the shores, the boats, the very riggings of the ships being alive with an excited and applauding multitude. Tivoli itself was brilliantly illuminated, and the evening terminated by a gorgeous display of fireworks.

On Friday, the 15th, Professor Virchow read his paper on Metaplasia. The Professor commenced by giving a summary of the different hypotheses of the several life processes during the first half of the present century; until about thirty years ago he offered the proposition *Omnis cellula e cellulâ* as the basis of a new theory. He then described the different forms of cellular processes which this new theory had by degrees taught us to distinguish, and amongst these he dwelt particularly upon metaplasia. By metaplasia Virchow understands the vital process which tends to organic change of the cells by producing new forms of tissue. The essential feature of this process is that the cells remain while the character of the tissue changes. Metaplasia is the basis of important pathological processes, without being itself pathological in nature; on the contrary, it is entirely a physiological process. In ossification we have a good example of metaplasia. Ossification never takes place in the original cells of the fœtus, but these first form a transition tissue, and, from this, by metaplasia, the bone tissue is constructed. Another example is the marrow, which to a great extent is formed by metaplasia of the bone cells. Next to the bone tissue comes fat as most subject to metaplasia. Most frequently it is converted into mucous tissue. Thus one may see the whole layer outside the meninges spinalis transformed into a gelatinous mass, which process is often called colloid degeneration. The same change can occur in lipomatous tumours, either partially or totally, the result being that they take the character of myxomata. As another example of metaplasia as the basis of a pathological change, Virchow named the enchondromata, which are developed from small pieces of cartilage that become loosened during ossification. Whilst Cohnheim thought that these and similar tumours always had their origin in fœtal formations, Virchow considered them as a rule to arise at a later period. Lastly, he dwelt upon the possibility of cells belonging to different classes of tissue changing by metaplasia into each other.

In the Surgery Section, on the same day Mr. Thornton (London) read a paper on Nephrotomy and Nephrectomy. Mr. H. Morris (London) and Mr. Bryant took part in the discussion which followed, the latter considering that Mr. Thornton had performed nephrectomy in cases where nephrotomy would have proved satisfactory.

In the evening, the King, as patron of the Congress, entertained the members at the palace of Christiansborg, the whole of which was thrown open to the guests. The King, Queen, and other members of the Royal Family conversed with the more distinguished guests, and in every way showed their interest in the progress of science. A supper was served in the great dining-hall and the adjoining rooms, all being one blaze of light.

On Saturday, the 16th, in the united sections of Diseases of Children and State Medicine, Professor Malling Hansen (Copenhagen), Director of the Royal Deaf and Dumb Institution, read a very interesting paper on the Normal Increase of Weight during Later Childhood. The paper was illustrated by tables. He showed how in many countries careful investigations had been made on the influence of nourishment on the growth and development of the human body. The value of these investigations was lessened by the facts that, as a rule, the children subjected to the inquiry were too few in number, and were only weighed during a short period. To prove the untrustworthiness of individual weighings, the speaker quoted the investigations made in Germany upon children who, during the summer, were at the so-called holiday colonies. Professor Hansen adopted the following method:—The 130 children of the Deaf and Dumb Institution are from nine to sixteen years of age; they were divided into eight classes according to their age, and each class was weighed separately every day on a centesimal weight, besides each individual was weighed once a month, and the result of these single weighings was used to correct that of the class in case any child should have been ill or absent. In this way the boys were all weighed every day at 6 o'clock in the morning and at 9 in the evening; the girls were only weighed once a day, at 2 P.M. Some of the most interesting results obtained were the following:—A child might weigh from 1 lb. to 2 lb. heavier at night than in the morning, and be upwards of 1½ lb. lighter in the morning than it was the evening before. From one evening to the next a child might increase 1 lb. or decrease ¾ lb. These results, which concern normal children, proved how unreliable the results must be when the intervals between each weighing are longer than twenty-four hours. Exercise, bathing, &c., did not seem to have much influence upon the weight; whilst, as regards eating, there was always an increase after a full meal. The speaker then proceeded to say, that during the year there seemed to be three periods in which a child's increase in weight varied: first, a period of decrease from the middle of May in each year to the middle of July; a period of increase of great importance from the middle of July to the middle of November; and then a period during which the child increased slightly but often remained stationary and might even lose in weight, from the middle of November to the middle of May. Altogether a child's increase in weight is limited to from one-fourth to one-fifth of the year, the rest of the time showing either loss of weight or compensation for loss. Besides the fixed periods of decrease there were often, even during the increase periods, sudden stoppages, lasting from six to fourteen days; after such a period the increase was sometimes greater than usual, but the stoppage was never thoroughly compensated for by the following increase. The frequency of this increase and decrease seemed to depend upon changes in the temperature, increase in temperature being accompanied by increase in weight and *vice versâ*, decrease of weight following rapid decrease of temperature often being considerable and of long duration. A great difference in the appetite was noticeable in the various months and even weeks, but with great regularity, the appetite being greatest in March and least in January. The boys ate one-fifth more than the girls, although the latter often increased more in weight. From the daily weights taken at the Royal Danish Deaf and Dumb Institution, it was shown that diet arranged after the latest scientific ideas was a failure. Professor Hansen concluded by saying that these mass weights taken in a number of institutions in all countries would be one of the best means of finding the nutritive value of various foods during a longer period. This paper, which was listened to with great interest, was much applauded, and gave rise to various remarks. The honorary presidents, Professors Rauchfuss (St. Petersburg) and Jacobs (New York) laid great stress upon the novelty and importance of these investigations, but they remarked that there was danger in considering that increase in weight

Digitized by Google

and fat and increase in health and strength were synonymous. To this Professor Hansen replied that it was hardly probable that a child could increase in health and strength without increasing in weight, and at the same time a child which continued to lose in weight must also lose in strength.

Professor Panum at the general meeting read a paper on Investigations of Food Rations for Men in a State of Health and of Disease, especially in hospitals, infirmaries, and prisons of different countries. He said that the investigations which had been made in the chemical composition of food were not widely enough known. It was not often that physicians were met with who had sufficient knowledge on this subject. He even feared that medical men who sanctioned diets for hospitals and like institutions often had not made the necessary investigations into the composition of the various aliments. This knowledge had been recognised as one of the principal branches of medicine, yet diets for the sick were too often based on old-world opinions. There were many points still disputed, but the principal facts were settled. No one would dispute the fact of the existence of nitrogen and carbon in food, and that it must contain both in larger quantities than leave the body in order to make up for those parts lost in the preparation. The speaker then drew attention to the investigations which had been made on the increase or decrease of the body in consequence of the supply of a sufficient or insufficient quantity of nourishment. He showed that the quantity of nitrogen given off in the urine was the same—supposing the quantity of albumen taken to be the same—whether the body was at rest or not. On the other hand, the quantity of carbon given off was larger when a greater amount of labour was performed; consequently the needed quantity of carbon would be greater when the body was active than when passive. These facts were settled. In reference to them estimates had been made of the amount of nourishment necessary for men, women, and children under different circumstances. It might be said that the hospital doctor did not need them, as the patient's condition would show whether the nourishment received was sufficient; but that was not the case. In these respects it was impossible always to attend to the patient's complaints, as these might arise from the plainness and sameness of the food. The dietary rules in various hospitals were so different that it was difficult to make any comparisons as to their results. However, Professor Panum had made a series of investigations in several hospitals where the dietary rules were somewhat similar. He had discovered in some hospitals that the amount of nourishment received was less than was necessary, but this was accounted for by the amount of food received from outside the hospital. He proposed that a system of investigation should be organised, the principal points of which had already been given in the programme of the Congress. Professor His, the president, thanked the speaker.

Professor Panum then took the chair, and the discussion as to the next place of meeting was commenced. Professor His read the following report. The meeting place for the next Congress had been considered by a committee consisting of the Congress Committee proper and the honorary members. The president had been in communication with Lyons, St. Petersburg, Rome, and various towns in Germany. As far as Lyons was concerned, it was almost out of the question to talk of meeting in France again before having been in Germany. The proposal to meet in St. Petersburg had presented so many difficulties that it had to be given up. A letter had been received from Rome saying that the Congress would be welcome in that town, but Professor Tommasi Crudeli had declared it impossible to meet there in August, which was the only convenient month for the European universities. Many circumstances were favourable to Germany as the next place of meeting, and Professor Virchow had promised the Congress a most hearty welcome. The choice, indeed, would have fallen on Berlin if a most hearty invitation had not been received from Washington, and the majority in the committee had finally decided in favour of that town.

Professor Billings returned thanks for the honour shown his country; Professor Rossander (Stockholm) returned thanks for the hospitality shown to himself and countrymen; and Sir Risdon Bennett for England.

Professor Virchow thanked the king and royal family for their patronage. Professor Panum then, in a few farewell words, closed the meeting.

The Etablissement National was the scene of the farewell entertainment, which was attended by about 2000 persons, including the members of the Congress and their ladies. The entertainment broke up about 1.30 A.M., the company separating with evident regret that a week never to be forgotten had so soon come to an end; and, in fact, the great hospitality of the Danish medical profession, the enthusiastic sympathy of the whole population, combined with fine weather in this beautiful country, had made this Congress one of the most interesting in the whole series.

THE FIFTH INTERNATIONAL CONGRESS OF HYGIENE.

(From our own Correspondent.)

CHOLERA AND QUARANTINES.

THE cholera epidemic has been the cause of some soreness among the members of the Congress. It can scarcely be said that it has been debated as an abstract question. It seemed rather as if there were certain nations and men who had been impeached, and were therefore called upon to make good their case against all. Undoubtedly there is a political reason which prompts certain Frenchmen to infer that but for English interference in Egypt the cholera would not have been imported into Europe. Of course, it is objected to this that we are equally interested, commercially, if not politically, in seeking to prove that quarantines are of no use. But an international congress of scientific men should not allow itself to be influenced by rival commercial and political interests. It should only seek to unravel the truth, whatever the consequences may be. Perhaps, however, the animosity was increased by the manner in which the case was presented. Dr. Dutrieux Bey of Alexandria, who, by the way, is not an Egyptian, but a Belgian doctor, thought to make his position as the opponent of quarantines all the stronger by attempting to prove that cholera broke out spontaneously, and was not imported. This was a most unfortunate manœuvre, for it put the real question at issue into the background, and deprived Dr. Dutrieux Bey of all support. The members were afraid to vote against quarantines, as they might be thus supposed to deny the Asiatic and transmissible character of cholera. In spite of the obvious danger of creating this confusion, Dr. Dutrieux Bey commenced his speech by explaining that he had personally examined the valley of the Nile, and there found many cases of cholera (notably on April 4th), showing that this disease had prevailed to a considerable extent before its presence was generally admitted. The sanitary condition of the Nile provinces had so deteriorated that he thought cholera had become indigenous to the soil. According to Collin and numerous authorities, the plague had a preliminary stage of a mild and endemic description; then, after sundry premonitory symptoms, showing the gradual development of receptivity, it broke out in its violent and epidemical form. The same might be said of cholera. Examining the death returns and the hospital papers of Toulon, he had found one death from cholera on January 17th, and at Marseilles there had been cases of cholera ten days before the arrival of the suspected ship. The distinction established between Asiatic cholera and cholera nostras was but an arbitrary and artificial device. The importation of cholera had become a dogma, and, like dogmas, was blindly and obstinately defended. But cholera was not particularly contagious; it was less contagious than diarrhœa. As in all ports there were always arrivals from doubtful districts, it was easy enough to find a culprit; but to prove the importation it did not suffice to show that a death had occurred; it was necessary to demonstrate that previously the country was absolutely free. Unfortunately, we always watched the entrance-door instead of looking inside. Thus, while Europe was busy establishing quarantines on the Suez Canal, nothing was done to remedy the internal condition of Egypt, and the result was an epidemic which swept away about 100,000 out of a population of less than 5,000,000. However limited the possibility of transmission, measures must be taken. But could it be said that quarantines were really useful? In 1852 cholera began at Cologne without any trace of importation. In Russia cholera was said to have been imported by a land route in 1832 and 1848, while it was supposed to have come by sea in 1865, and broke out spontaneously at other periods. As a

Digitized by Google

matter of fact, cholera was endemic in Russia. Dr. Dutrieux Bey then quoted a number of instances where ships had brought cholera patients and yet no epidemic ensued, nor had the railways in India facilitated the spread of the disease. Quarantines were useless, as they were only established after the germs had been introduced, and should be replaced by sanitary inspection and rigorous disinfection. This was the policy that had been successfully carried out by Norway, Sweden, and Denmark. But for the fear of quarantine, captains of ships would not conceal cases of illness, and the public authorities would not be tempted by a false sense of security to neglect the real methods of fighting epidemics.

Dr. Proust, in reply, urged that the International Epidemical Conference, held at Vienna in 1874, was unanimous on the necessity of maintaining quarantines against Asia, and was only divided in opinion as to the possibility of establishing quarantines between the different countries of Europe. At great length he proceeded to prove that undoubtedly cholera had been imported, notably after pilgrimages to Mecca. Quoting the report of M. Mayé, who had been sent by the French Government to Egypt, Dr. Proust remarked that the sanitary condition of Damietta was not more unfavourable than usual when the cholera broke out. Even Dr. Hunter could not recognise the spontaneity of the outbreak; though, to please his Government, he was forced to say it was "a resuscitation." He then accused Dr. Dutrieux Bey of not having spent sufficient time at the hospitals studying the papers, and maintained that, far from Toulon and Marseilles being prepared for the cholera, it so happened that the health of these towns was exceptionally good at the moment of the outbreak, and there was a remarkable absence of diarrhœa or cholera nostras.

Dr. Dutrieux Bey at once replied that he denied the competence of M. Mayé, who had only spent a few hours at Massourah, and had not visited the Delta. Why did they not reveal the names of those convenient stokers who brought the cholera? And who was there who could satisfactorily explain the difference between Asiatic cholera and cholera nostras? The Vienna Conference had failed to show the efficacy of quarantines, nor could it venture to say that cholera was not endemic in Russia, or to put aside the objection that the Caspian Sea was a Russian lake which Europe could neither watch nor control. Why, then, when cholera might cross unchecked the broad frontier line of Russia, was so violent an attack made upon the Suez Canal?

Dr. Brouardel thought there were some points of common agreement. He was quite willing to suppress the term cholera nostras; but a cholera does exist which does not spread; it lives and dies in one place. Another form of cholera is transmissible. So long as cholera was limited to its birthplace nothing much was said about it; but if, on June 21st, the alarm was given, it was not because there were cases of cholera at Toulon, but because the cholera had spread from village to village in the south of France. The post-mortem examinations which Dr. Brouardel had made last year at the Paris morgue revealed no less than six cases of cholera. Yet this was of little importance, and the thirteen deaths at Toulon in one day would have been treated in the same light but for the fact that it then became clear the disease was of the second and transmissible type. It appears, however, that the Mayor of Toulon explained to Dr. Brouardel that there were in reality only four deaths from cholera on that memorable day, the mayor having falsely registered all deaths from diarrhœa as cholera, so as to terrorise the population and clear the town. No doctor at Toulon accused the *Sarthe* of importing the disease, and if quarantines were badly managed, they might be improved instead of abolished.

Dr. Zoëros Bey, the representative of the Ottoman Government, then spoke with much animation in favour of quarantines. The Crimean epidemic had been imported. In 1865 another epidemic was introduced by a ship belonging to the State, and resulted in the death of about 30,000 of the Sultan's subjects. On the other hand, in 1860 an individual having brought the cholera to a small village on the Bosphorus, a cordon was established round the village and the epidemic did not spread. Later on several cases occurred in a hospital through the use of a room where cholera patients had been treated during the previous epidemic; by placing the patients under canvas and isolating them no further harm occurred.

Dr. Proust now spoke once more. Together with his fellow delegates from the French Government, he had questioned thirty-five doctors at Toulon and more than 200 at Marseilles; why should the opinion of one doctor from Egypt be accepted against them? Was this one solitary voice to upset the system Europe had instituted to protect itself against epidemics?

These remarks elicited a reply from Dr. Dutrieux Bey, and he insisted that no importation had been proved before the existence of receptivity. As for the evidence of the doctors mentioned by Dr. Proust, he wished to know on what basis inquiries should be conducted—verbal assertions or death-certificates?

Dr. Rochard spoke once or twice on the French side.

Finally Dr. Crocq of Brussels sought to discuss the matter in a calmer tone. "Is cholera transmissible? Yes, it is; but," he added, "receptivity is not yet sufficiently well known to base a system on it. Cholera, though contagious, miscarries in certain cases. In some towns it kills ten persons, in others thousands. Sometimes there are but one or two cases, sometimes 10 per cent. of the population is swept away. This difference has not been sufficiently studied. But as the disease is transmissible, we must adopt quarantines. At the same time, we shall avoid exaggerations. The best things perish by exaggeration. Land quarantines are impossible. They may spread the contagion, but can never prevent it. In certain circumstances they might, however, be applied. Notably in the steppes of Russia, where surveillance is easy and in those cases useful." The same might be said of certain parts of Asia or Africa; places, for instance, where there is but one road. This proved that he was in favour of quarantines in seaports, but on condition that they were applied reasonably, and not in a vexatious manner. The germ being principally transmitted by intestinal evacuations and in soiled linen, it was not so difficult to stamp out the cause of epidemics.

The section numbered fifty-one members, and the greater part rose to vote against Dr. Dutrieux Bey, while the one solitary Englishman present voted for him. He, however, explained that his vote was given as a protest against quarantines, and not as endorsing Dr. Dutrieux Bey's views on the etiology of cholera. Dr. Dutrieux Bey was not, however, to be beaten. Every ensuing morning he sought to reintroduce the question; and, as in the interval Dr. Corfield, Dr. Sweeting, and other medical men arrived from London, there was every reason to anticipate that a better fight could be made. The majority, however, clamoured that they had had enough of the question; and, as Dr. Raymondaud was to read a paper on the Organisation of a Universal Society against Epidemics, it was decided that the question of quarantines should be taken up again in discussing Dr. Raymondaud's proposals. This paper was, however, not read till the end of the last sitting but one. The principal suggestion was the union of all sanitary societies and authorities to raise funds and form a limited liability company for the drainage of the Ganges valley, and thus attack the cholera at its basis.

The following morning the section gathered in force. Dr. Dutrieux Bey opened the debate by reading a short paper. The Congress had decided that quarantines ought to be improved, but had not said how such improvement should be attempted. In theory, quarantines were to be applied at the first case of Asiatic cholera and maintained till after the last case. In practice, however, this was rarely, if ever, done. It is impossible to ascertain the first or the last case, and quarantines are established too late and abolished too soon to be of any real service. Also the regulations and restrictions are constantly defied. Consequently, Dr. Dutrieux Bey moved:—First, that in fixing the duration of quarantines the time allotted should be based on the time required to submit the ship to a rigorous sanitary and medical inspection and disinfection; and further, to prevent any misunderstanding, it would be advisable to substitute the words "sanitary control" for the word "quarantine." Secondly, that it is desirable to modify as promptly as possible the quarantines actually established in the Mediterranean ports so that their duration may be limited to the time necessary to carry out a thorough medical and sanitary inspection and disinfection.

The moment this resolution had been read out, Dr. Zoëros Bey excitedly protested that the Ottoman Government would never adopt such a measure, as Constantinople had been saved year after year by quarantines. Amid much clamouring, Dr. Corfield commenced a carefully prepared speech, by remarking that formerly all Englishmen were in favour of quarantines, but that now opinion was as unanimous in the contrary direction. At this point, Dr.

Digitized by Google

Rochard rose and, together with other French doctors, loudly objected to Dr. Corfield's being heard. The question had been decided, and they would not allow it to be revived. An Englishman then protested that the previous vote was complicated with the question of the character of cholera; that a vote on the simple question of quarantines had not been taken, and that, as England was the country which was most attacked, it was only fair to hear the distinguished professor of hygiene, who had prepared a defence of the English policy. Dr. Rochard, however, protested that there was no desire to attack any nation; the name of England had never been mentioned, so Dr. Corfield need not trouble himself to defend his country. This, of course, was a mere play of words; for, though the name of England had not been mentioned, there could be no doubt that we are accused of interfering with quarantines in the Red Sea, and of allowing commercial interests to take precedence over the interests of the health of Europe. Nevertheless, Dr. Corfield was not heard, and the only concession made was to allow Dr. Dutrieux Bey's resolution to be put to the vote without any discussion. In spite of this disadvantage, twelve members stood up for the resolution, and only twenty to twenty-four against it. There must have been more than fifteen abstentions. This result caused much surprise, and was considered a moral triumph for the minority. Of the twelve voters against quarantines, three were English, and the remainder for the most part Dutch and Swiss.

The Hague, August 28th, 1884.

THE BRITISH DENTAL ASSOCIATION AT EDINBURGH.

THE British Dental Association, which occupies the same position with regard to the dental profession as the larger and more widely known British Medical Association does to the medical, has just been holding its fourth annual general meeting at Edinburgh, under the presidentship of Dr. John Smith, LL.D., a well-known practitioner of that city. The proceedings commenced on Thursday, the 28th ult., when the local "Scottish" branch held its annual meeting. This was followed by a reception of the members of the Association by the president and the Lord Provost of Edinburgh (Sir George Harrison) at the Royal College of Surgeons, of which Dr. Smith is also president. A very interesting collection of models, pathological specimens, and novelties in dental apparatus was arranged for inspection, and several members gave practical demonstrations of different methods of filling teeth, &c. In the evening there was a conversazione at the Forestry Exhibition, at which the Lord Provost again did the honours.

The serious business of the meeting began at half-past nine on Friday morning and occupied the entire day. At the business meeting Mr. F. Canton, the hon. secretary, reported that there had been a decided increase in the numerical strength of the Association during the past year, though not quite as great as might have been expected, about fifty new members having joined. It now included five branches, three in England and two in Scotland, whilst a fourth English branch was then in process of formation. In other respects the present condition and prospects of the Association might be regarded as satisfactory. It was decided to hold the next annual meeting at Cambridge, and that it should be extended over three days, on account of the increased amount of business which had to be disposed of. Mr. R. White of Norwich was nominated as president-elect.

A short address from Mr. John Tomes, F.R.S., the Chairman of the Representative Board, who was unable to be present owing to ill-health, was read by Mr. J. S. Turner, the vice-president. It explained the causes which had led to the partial failure of the prohibitory clauses of the Dentists Act, which had given rise to a certain amount of dissatisfaction amongst the members of the Association, a cry having been raised that the Representative Board was neglecting its duty in not prosecuting the numerous quacks who were defying the provisions of the Act all over the country. Mr. Tomes pointed out that the dental was scarcely worse off in this respect than the medical profession, the Legislature having always steadily refused to make the act of medical practice by unqualified and unregistered persons penal. No fault had been found with the educational clauses of the Act, and from the gradual operation of these a steady improvement in the state of the profession might confidently be expected. If full force were given to these, they might lightly regard the mere prohibitory sections of the Act.

The valedictory address of the retiring President, Mr. C. Spence Bate, F.R.S., of Plymouth, was read by the hon. secretary, Mr. Bate having gone to Canada to attend the meeting of the British Association. He called attention to the many important questions still remaining unsolved in the department of dental surgery, and pointed out that the solution of some of these was of great importance for the purpose of affording a sure basis for sound curative treatment. Much might be done by the persevering efforts of enthusiastic individuals, but unfortunately individuals were very prone to approach questions of this kind with a strong personal bias. Thus, the cause of decay of the teeth had been studied by many, and the futility of individual research was well exemplified by the result that almost every inquirer had founded a new theory which was identified with the idea preconceived by himself before ever he commenced to study the subject. Mr. Bate advocated the appointment of small committees for this purpose, and recommended also the extension of the system of collective investigation to dental diseases, pointing out that with regard to many pathological changes in the mouth a carefully considered report of a series of cases would be of far greater value than the present system of recording remarkable examples, which could only demonstrate the possibilities of abnormal conditions, and did but little to advance real knowledge.

Dr. John Smith then took the chair, and delivered his inaugural address. Those present were, he remarked, called together as the representative and supervising assembly, and to a certain extent as the administrative convocation for the dental profession throughout Great Britain. It might be argued that as there existed a Dentists Act enunciating the law which regulated dental practice, that long before the Association existed there was at least one great dental school, and one great surgical corporation conferring on the students of that school a high distinctive qualification; that at the present day there were many additional complete and reliable schools of dentistry, and a full and recognised dental qualification was conferred in each of the three divisions of the kingdom; that over all these there was a court of supervision provided in the General Medical Council, and a safeguard and guarantee against illegal practice and pretenders in the Dentists' Register—that, in the face of such a state of matters, little seemed left for an association such as theirs to do. The answer was that by the various schemes referred to, the machinery for education, examination, and qualification had been provided; but some effective power was required to render this machinery available, and to ensure the work it was intended to perform being done, and done thoroughly; and, besides this, that an opportunity should be afforded for the collective voice of the profession being heard on all important questions. And whilst the Association thus acted as a valuable and powerful element of control, it also served to establish and maintain friendly feeling as well as scientific intercourse amongst its members. Dr. Smith then dwelt upon the importance of the executive carrying out its functions with the utmost care and deliberation, and followed Mr. Tomes in deprecating hasty and inconsiderate expressions of opinion on the part of individual members. He concluded with an eloquent peroration, in which he welcomed his audience to the "stately Edinburgh throned on crags," and described its beauties.

Papers were next read by Mr. Robert Reid of Edinburgh, on the Application of Dental Science in the Detection of Crime; on the Prevention of Caries, by Mr. Henry Sewill of London (see page 402); on the Treatment of Fractures of the Inferior Maxilla, by Mr. Walter Campbell of Dundee; on Abscess of the Antrum, by Mr. G. W. Watson of Edinburgh; on Educational Centres, by Dr. Walker of London; and on the Prevention of Irregularity, by Mr. J. R. Brownlie of Glasgow. Some of these papers gave rise to a considerable amount of discussion.

In the evening about a hundred and fifty members and visitors dined together at the Waterloo Hotel. Amongst the visitors present, several of whom had also attended the afternoon meeting, were the Lord Provost and two of his brother magistrates; Dr. George Balfour, President, and Dr. Peddie, ex-President, of the College of Physicians of Edinburgh;

Digitized by Google

Dr. Littlejohn; Professors Maclagan and Annandale; Drs. Fergus, Keiller, and David Wilson; Mr. Imlach, and others.

On Saturday there was an excursion up the Firth of Forth, in a steamer specially chartered for the purpose, to view the preparations for the Forth bridge now in process of construction, and a very successful meeting was thus brought to a close.

HEALTH OF THE ARMY.

No. II.

THE average strength of the white troops serving in Ceylon in 1882 was 990, among whom the admissions into hospital were in the ratio of 1197, the deaths of 8·08, the invalids sent home 56·56, and the mean sick 62·98 per 1000. These are all considerably lower than in 1881, but, with the exception of the deaths, above the average of the last few years. The death-rate has been very low, amounting only to half the average, the reduction being in the classes of fevers, tubercular diseases, and general injuries. There was only one admission and one death from enteric fever.

In China and the Straits Settlements the admissions from a strength of 1663 men amounted to 953, the deaths to 6·01, the invaliding to 52·31, and the mean sick to 50·37 per 1000. The admissions and deaths were much below the average, but the invaliding and mean sick above it, though lower than in 1881. Fevers and diseases of the digestive system gave rise to the largest numbers of admissions. There were only three cases of enteric fever, two at Hong-Kong, and one, which proved fatal, at Penang. No case of cholera occurred during the year.

In India the average strength of European troops was 57,344, from whom the admissions into hospital were 1437, the deaths (including those of invalids) 12·82, the invalids sent home 34·14, and the constantly sick 66·38 per 1000. These ratios, with the exception of the mean sick, were considerably lower than in 1881, and were also under the average of the last ten years.

The sickness, mortality, and mean sick in Bengal were higher than in the other two presidencies; the ratio of admissions into hospital was 1555, of deaths 13·93, and of constantly sick 69·83 per 1000. Compared with the average of preceding years these results are very favourable as regards the death-rate, but higher as regards admissions and mean sick. Paroxysmal fevers were, as usual, the chief cause of sickness, having furnished upwards of one-third of all the cases. The highest death-rate was from diseases of the digestive system, but it was very little above that from enteric fever. The latter gave rise to 7·4 admissions and 2·83 deaths per 1000 of the strength. The stations at which it was most prevalent and fatal were Sitapur, Cawnpore, and Lucknow. At the first of these the admissions were 53·40 and the deaths 18·98 per 1000 of the strength, at Cawnpore they were 18·56 and 11·34, and at Lucknow 13·84 and 5·81. At Sitapur the disease occurred in a wing of the Lincolnshire Regiment, which arrived at the station from Gibraltar on the 13th of February, no case of enteric fever having occurred in it up to that date. On the 23rd a man was admitted with simple continued fever which afterwards proved to be enteric. The disease continued to prevail till June 9th, 43 cases having occurred during that time. A case of this disease had occurred at the station in the end of January in the corps which was relieved by the Lincolnshire Regiment. It is noteworthy that in the other wing, which came out at the same time from Gibraltar, but which was sent to Benares, no case of enteric fever occurred till July, when two men were admitted, and in August two more, after which it ceased. At Cawnpore the admissions amounted to 18·56 per 1000 and the deaths to 11·34; and all occurred, not in a newly arrived corps, but in one which had been two years and four months in the country, and might therefore be supposed to be in a great degree acclimatised. The disease prevailed in it from the end of February till the end of June. The officers, women, and children, and the Royal Artillery at the same station escaped it entirely. No details are given of the outbreak at Lucknow. Cholera did not prevail to any extent generally throughout the command, the admissions having been only 2·0 and the deaths 1·24 per 1000. At Fyzabad and Benares, however, it occurred as an epidemic; at the former place the admissions were 35·85 and the deaths 24·72 per 1000 of the strength, and at the latter 27·71 and 15·11 respectively. The disease occurred chiefly in the third quarter of the year. No details are given in the report respecting these epidemics except that at Benares "the men were promptly encamped out with satisfactory results," while at Fyzabad "after some temporising, the barracks and hospital were vacated, and the outbreak ended, but whether naturally by exhaustion of the period of its lifetime, or by the good effect of removal from infected buildings, is not apparent."

The strength of the troops in the Madras command was 10,817; the admissions into hospital were 1069, the deaths, inclusive of those of invalids, 11·00, and the mean sick 59·39 per 1000; the latter was slightly above, but the other two ratios were considerably under, the average of the last ten years. Diseases of the digestive system were the most prevalent and fatal in the command, and next to them fevers. Enteric fever was the cause of 4·3 admissions and 2·13 deaths per 1000. Bangalore was the station which furnished the greatest number of cases, the admissions having been 11·30 and the deaths 4·16 per 1000 of the strength stationed there. "No insanitary condition in or about the barracks likely to influence the causation of this disease could be discovered, but it is remarked that the impure nature of the drainage flowing into the Ulsoor Tank, and other sources of pollution, must always render the water-supply open to suspicion." Although cholera was very prevalent among the civil population, there were only 15 cases and 9 deaths among the troops, being in the ratio of 1·4 and 0·83 per 1000; 11 of these and 4 deaths occurred on the march, 7 with 4 deaths between Kamptee and Bangalore, and the others among troops in the boats on the river after leaving Tonghoo *en route* for Bangalore. One death from snake-bite occurred at Secunderabad; the man lived about thirty-two hours after the receipt of the injury.

In Bombay, from a force of 10,197 non commissioned officers and men, the admissions were 1406, the deaths 10·79, and the mean sick 61·47 per 1000; the two former being much under and the latter above the average of preceding years. The most prevailing cause of sickness was paroxysmal fevers, which gave rise to more than one-third of the admissions. Enteric fever was the most fatal disease, there were 43 cases and 18 deaths, being in the ratio of 4·2 and 1·77 per 1000. At Nusseerabad 13 cases and 8 deaths occurred in a force of 668 men; at Colaba there were 9 cases, of which 4 proved fatal, but 8 of these were landed from H.M.S. *Euphrates*, the disease having been contracted at Alexandria. Cholera furnished only 10 cases and 7 deaths, and of these 6 cases and 5 deaths were at Nusseerabad in the third quarter of the year.

The relative health of the different arms of the service for the year 1882 is shown in the following summary for the whole force in India.

Per 1000 of mean strength.	Admitted.	Died.	Invalided.	Constantly sick.
Cavalry ...	1419 ...	10·87 ...	49·43 ...	68·27
Artillery ...	1510 ...	12·50 ...	48·94 ...	68·33
Infantry ...	1435 ...	12·12 ...	31·39 ...	65·85

The artillery therefore show the highest rate of sickness and mortality and the cavalry the lowest, but the infantry had the lowest proportion constantly in hospital.

The most interesting chapter in the report is that which relates to the health of the troops serving in Egypt from July 17th to the end of the year. The admissions into hospital during that period were in the annual ratio of 2322, the deaths from all causes of 88·90, and the invalids of 521 per 1000. The history of the period is divided into two, the first portion relating to the Expeditionary Force from July 17th to October 9th, and the second to the Army of Occupation from October 10th to December 31st. The annual ratio of mortality of the former was 76·57, and of the latter 100·69 per 1000. The history of the Expeditionary Force was given by Sir J. Hanbury, the Principal Medical Officer, and Dr. Marston, the Sanitary Officer of the Army, in the report for 1881 (see THE LANCET, November 24th, 1883). The principal causes of mortality in the Army of Occupation were enteric fever and dysentery. The prevalence and fatal character of the fever were due to a combination of causes. The soldiers were mostly young men, they suffered from heat, hard work, fatigue, indifferent food, and foul water, and all the conditions necessary for the development of epidemic disease were present in Egypt generally, and Cairo in particular. "Every available

Digitized by Google

barrack and public building in Cairo, and in Egypt generally, was in so foul a state as to be uninhabitable by Europeans, and it was impossible to find any camping ground affording sufficient space, with water supply available, that was not, for military considerations, too far distant from Cairo itself." In the report the question is discussed how far in a campaign "preventable diseases can be prevented," and it is clearly shown that the conditions under which war is waged render this practicable only to a very limited extent. This section of the report deserves careful study, as showing the difficulties with which the medical department have to contend in their endeavours to preserve the health of the troops. There is an interesting account, taken from the *Archives de Médecine et de Pharmacie Militaires*, 1883, of the prevalence of enteric fever in the French Army of occupation of Tunis, North Africa, which shows them to have suffered to even a greater extent than our troops in Egypt, the admissions having been in the ratio of 210 and the deaths of 51·95 per 1000; while in Egypt the ratios were 93 and 35·98. In connexion with the death-rate in Egypt, it may be stated that of 171 cases of sunstroke and heat exhaustion, caused by the newly landed troops having to march in the desert in the midday sun, only 3 died, a result highly creditable to the medical officers.

In the appendix to the volume a very interesting medical report of the Eastern Soudan Expeditionary Force is given by Brigade-Surgeon McDowell, who was Principal Medical Officer. Full details are given of all the arrangements, which appear to have been very judicious and well carried out. The campaign lasted from Feb. 15th to April 6th, a period of fifty-one days. The average strength of the force was 4018; the admissions into hospital were 512, and the deaths, all in action, were 126; being in the ratio of 127·4 and 31·36 per 1000 of the force. If these numbers are reduced to an annual ratio they give 912 admissions and 224·4 deaths per 1000. Nearly half of the admissions were from wounds and injuries. An interesting table is given of the seat of the wounds and also of the projectile or weapon by which they were inflicted. Two-fifths of those killed in action were wounded in the chest, one-fifth in the head, and nearly one-fifth in the abdomen; while of those admitted into hospital one-third were on account of wounds of the upper and nearly one-third of the lower extremities.

There is also in the appendix a report on the cholera epidemic in Egypt during 1883, by Surgeon-General Irvine, the Principal Medical Officer of the troops. The first cases of the disease were reported at Damietta on June 22nd; it then appeared at Mansourah, and, in spite of cordons, spread over the country, and on July 15th cases were reported in Cairo. On the 21st the first case among the troops occurred at Suez, and on the 23rd it broke out among those at Cairo. Notwithstanding every precaution being adopted by evacuating the barracks, encamping the troops, and moving the camps when requisite, the disease spread among them; and before the termination of the epidemic 194 cases and 142 deaths were reported, "being in the ratio of 2·9 and 2·1 per cent. of the strength." The disease was of a very virulent type, 73 per cent. of the cases having proved fatal. Contrary to the general experience in cholera epidemics, the attendants on the sick suffered in a much greater degree than the rest of the troops, and this was also the case with patients in hospital compared with the healthy men. No information is given in the report as to any special precautions being taken to protect the attendants on the sick, a point to which much importance is attached in the instructions recently issued by the Royal College of Physicians. A table is given of the cases and deaths among temperate, intemperate, and men of irregular habits; but as the numbers living of each class are not stated, it is of comparatively little value; the proportion of deaths to cases was almost identical in the three groups. The ages and length of service of the men attacked and of those who died are also given, but the information is defective in the same respect of the numbers living being omitted. The proportion of deaths to cases was higher among the old than the young soldiers.

During 1882 the number of recruits examined medically was 45,423; of these, 19,294 were rejected as unfit, being in the ratio of 425 per 1000 inspected. In the preceding year the ratio was 432. From this, however, should be deducted a number of men rejected as being "under height" and "apparent age not in accordance with General Orders," as such cases ought not to have been brought before the medical officers by the recruiting parties. Exclusive of these, the proportion of rejections would amount to 379 per 1000, or exactly the same as in the preceding year. Upwards of one-third of all the rejections was for being "under chest measurement." Next to this the most frequent cause of rejection was "defective vision," the proportion being 35 per 1000 examined. Muscular tennity and debility was the reason assigned for rejection in 27, and disease of the heart in 21 per 1000. Of recruits inspected by army medical officers, 435 per 1000 were rejected as unfit, while the proportion among those inspected by civil medical practitioners was only 140; but of the men passed by the latter, 224 per 1000, or nearly one-fourth, were subsequently rejected on joining at head-quarters. England and Wales furnished 737 per 1000 of the recruits, Scotland 106, Ireland 145, and the colonies and foreign countries 12. Omitting the last on account of the small numbers, the proportion of rejections was highest among the Irish and lowest among the Scotch, the difference amounting to 50 per 1000. Taken by arms of the service, the rejections were highest in infantry regiments and lowest in the Foot Guards, the proportions being 445 and 279 per 1000. The return of the ages of the recruits shows a marked decrease of those under nineteen, a marked increase at the age of nineteen to twenty, and a slight decrease of those of twenty and upwards. We fear, however, that but little reliance can be placed upon these results, as there are no means of ascertaining the correct age of the men, and their statements are not in the least to be relied on. It seems very probable that the difference in the younger ages was simply the result of a mis-statement on the part of the younger recruits, for the purpose of bringing themselves within the age at which they would be eligible for enlistment. As regards the height of the recruits, there has been a marked decrease in those between 5 ft. 4 in. and 5 ft. 6 in., and an increase in the numbers at all heights above that. There has also been an increase in the proportion of recruits at the higher weights, and chiefly of those from 130 to 140 lb. A new table has been introduced, giving the chest measurement of the recruits at different ages; it shows that in 10,000 there were 3720 from 34 to 35 inches, 2613 above 35 inches, 2366 from 33 to 34 inches, and 1301 under 33 inches; there are no data for a comparison of these numbers with previous periods. The returns of the state of education of the recruits show a decrease in the proportion unable to read and write of 24 per 1000. Of the recruits examined, 928 per 1000 had marks of vaccination, 24·9 of small-pox, and 47·1 of neither. This shows a decrease of 10·2 per 1000 on the numbers bearing marks of small-pox, but the proportion having no marks remains unchanged. The value of vaccination is borne out by the results as regards small-pox in the army during the year. There were only 14 cases and 1 death among the soldiers serving at home, 44 cases and 4 deaths in India, and 2 cases with no death in the colonies. Among the women at home and abroad 14 cases occurred and no death, and among the children 11 cases and 1 death.

In addition to the papers already noticed relating to the Egyptian expedition, the appendix contains others of considerable interest. Of these we may specially note the report by Professor De Chaumont on the Hygienic Exhibition at Berlin in 1883. He was sent to Berlin with instructions "to report upon any exhibits that might be usefully adopted in our service so far as medical and hygienic appliances went." The result of a careful examination led him to the conclusion that there was "comparatively little that is new, or that could be usefully adopted in our service." He has given a brief account of these exhibits under the headings of (1) the arrangements for conveying sick and wounded in time of war; (2) certain surgical appliances; (3) plans of hospitals and barracks; (4) exhibits of hygienic apparatus; (5) miscellaneous. Under the first of these he describes especially a new spring military stretcher by C. Epner, Berlin, which appears to possess considerable advantages. In the second group he calls attention to "Esmarch's turf or peat dressings, which seem to be very successful; they are absorbent and antiseptic, and may be left for a long time"; and also to Dr. Walcher's wood-wool, which appears to answer well. Among hygienic appliances a drying apparatus by Oscar Schimmel and Co. of Chemnitz appeared to deserve particular notice, as accomplishing its object very efficiently, and being free from most of the objections which appertain to drying apparatus in general. Dr. De Chaumont thinks that a Schimmel's apparatus in each barrack for the purpose of drying the men's clothes when they come in wet would have an important influence in the prevention of serious disease.

Digitized by Google

Among other papers of interest in the appendix we would refer our readers to a case of death from snake-bite; a case of poisoning by iodoform, not fatal; an outbreak of fever on board of the War Department ship *Stanley* in the Mediterranean; and of enteric fever among the troops at Athlone.

The usual list of operations performed at Netley is given, with notes by Surgeon-Major Tobin, the Assistant Professor of Military Surgery. They were 45 in number, of which 2 terminated fatally—one after amputation of the leg at the junction of the lower and middle third of the femur, and the other after excision of the hip-joint. Both men had been wounded at Kassassin.

We cannot close our notice of this volume without expressing our regret at the absence again of the "report of the progress of hygiene for the year," begun in 1860 by the lamented Professor Parkes, and continued till last year by his successor, Dr. De Chaumont. We also miss any contribution from the medical division of Netley Hospital. It is to be regretted that the splendid opportunities of this large hospital are not turned to better account in the interests of the profession, and especially of the medical officers of the army.

DISINFECTANTS AT THE HEALTH EXHIBITION.

IN the East Annexe, close to Messrs. Doulton's pavilion, many of the disinfectants at present in vogue are collected. About twenty manufacturers exhibit; but there is, on the whole, but little novelty calling for notice. The coal-tar compounds, thymol and a few other aromatics, permanganates, and sulphurous acid, nearly exhaust the list. A few bear fancy titles, such as "sanitas," "Jeyes' perfect purifier," "affinitan," and "antimicrobe." The first of these is the well-known and very interesting invention of Mr. Kingzett. Its most active agent is peroxide of hydrogen, generated by the oxidation of turpentine, and present in very considerable quantity. There can be no doubt of the real value of sanitas. It is non-poisonous, agreeable in odour, capable of being used in many forms, and above all is an active, if not very powerful deodoriser. It has attained and deserves great domestic popularity, but we cannot regard it as a sufficiently powerful agent for dealing with zymotic disease. Much the same may be said of thymol, the eucalyptus preparations, and Mr. Wheeler's pixene, which last is an elegant pine-tar antiseptic.

Several manufacturers exhibit carbolic acid and its preparations; but the place of honour must certainly be assigned to Messrs. F. C. Calvert and Co., by whom this most important and valuable compound was first introduced to commerce. It still takes a very high place as an antiseptic, although its disagreeable smell and weak deodorising power are serious drawbacks to its general use. Messrs. D. and W. Gibbs, Messrs. M'Dougall Brothers, and Messrs. Mackey, Mackey, and Co. also exhibit carbolic preparations, and the last-named firm many vegetable and mineral disinfectants in addition.

In a case near the southern end of the gallery, Messrs. Boake and Co., of Stratford, show the new and important disinfectants of Professor Tuson, the scientific peculiarities of which are fully described in a handbill. The liquid is essentially a solution of chloride of zinc, saturated with sulphurous acid. It is unnecessary to speak of the sanitary value of these two agents. Each occupies a front rank in the list both of antiseptics and deodorisers; each supplies what the other lacks. The liquid properly diluted for use has no injurious action on metals or textile fabrics, and but little smell, so that while it destroys foul smells, such as that of sulphuretted hydrogen, it leaves none behind it. The solid has still more scientific interest. It is essentially a mixture of sulphite of lime, sulphate of alumina, and sulphate of zinc. When exposed to the air, it slowly absorbs moisture and evolves sulphurous acid according to the following equation:—

$$Al_2(SO_4)_3 + 3\,CaSO_3 = 3SO_2 + 3\,CaSO_4 + Al_2O_3.$$

When water is added to the powder, sulphurous acid is evolved with greater rapidity, while the sulphate of zinc increases the antiseptic power of the mixture. We can testify that both the solid and liquid are safe and harmless in a sick room, when used with ordinary care, and are also really trustworthy disinfectants.

As carbolic acid was introduced by Messrs. Calvert, so undoubtedly was alkaline permanganate by Mr. Condy. Condy's fluid is too well known to require description. Opinions still differ as to its trustworthiness as a disinfectant, but all must agree that it possesses much real value, and has been a boon in thousands of households. Several of the disinfectants exhibited under fancy names appear to contain the same compound. More novel and decidedly useful is the sulphur disinfectant of Mr. Overbury, of Alcester, which is simply a cake of sulphur with wood shavings embedded in it. Everyone knows that it is not easy to make sulphur burn quietly to the end, and in this case the wood acts as a wick, easily lighted and causing steady combustion. For ordinary house fumigation, one pound of sulphur should be burned to each 1000 cubic feet of space.

Several contrivances for the automatic disinfection of watercloset-pans are shown in action in the same annexe, and one or two may be briefly noticed. The London Patent Automatic Disinfection Company exhibit an apparatus by which a small and definite quantity of any suitable disinfectant is made to flow into the pan with the water, the reservoir requiring renewal but seldom. Even more ingenious is the Austin porous disinfector, which consists of an ordinary porous case filled with some powerful disinfectant, and suspended in the small tank or water-waste preventer, which supplies the closet. It is said that a single charge will last for more than a year, but care must of course be taken in the choice of a suitable disinfectant.

THE PROGRESS OF CHOLERA.

THE two most important events of the week are the steady spread of cholera in Italy and the extension of the disease into Spain. Northern Italy is now suffering from a considerable epidemic, and the disease having attacked some of the more populous towns where the sanitary arrangements are none of the best, it becomes difficult to form an opinion as to the course which the epidemic may assume. The large number of attacks in Spezia, a daily mortality there already reaching some sixteen or twenty, and the flight of the inhabitants to other towns and even to the mountains, form the most serious elements in connexion with the outbreak. The city of Naples is now also unquestionably infected, and the total attacks in the country generally have reached as high as one hundred and twenty-two, with over seventy deaths a day. Unfortunately the principal reliance still is in troops who form sanitary cordons, and in fumigations; whereas if the money spent on these measures were even now devoted to sanitary cleansings some substantial good might result. The infection of Spain has apparently been brought about by sea, and it is supposed that persons from Cette have made their way thence by a circuitous route to Alicante, carrying infection with them. The disease is fortunately not at present of a virulent type, but the inhabitants of Alicante could not be prevented from fleeing inland, and at Novelda, in the same province, deaths have already occurred. The outbreak at Toulon and Marseilles is steadily diminishing, and such fresh cases as occur in the neighbourhood of those two cities, as also at Perpignan and in its vicinity, are less numerous and less severe than they were.

We learn from Cardiff that two members of the crew of the Italian steamer *Abyssinia*, which arrived off that port on the 29th ult., were found to be suffering from symptoms which had followed suspicious diarrhœa, vomiting, &c. They were removed to the hospital on the Flatholm Island. A third man suffered from somewhat similar symptoms later on. One of the men gradually sank and died on the 3rd inst., the body being buried at sea. No farther sickness has occurred, and all precautions have been taken.

The Academy of Medicine at Paris adopted, on the 2nd inst., a resolution in favour of holding an administrative

Digitized by Google

inquiry into the conditions in which cholera made its appearance, the progress of the epidemic, its mode of propagation, intensity, and duration. It also affirmed the desirability of establishing an International Board of Health, as also municipal boards, on the model of that of Brussels, in the large towns. A note was read from M. Bourquet, of Aix, showing that cholera was not imported into that town by refugees from Toulon or Marseilles.

QUARANTINE AND INFECTED PORTS.

THE following notifications appear in the *London Gazette* of Aug. 29th and Sept. 2nd.

Five days' quarantine has been proclaimed at Bahia on arrivals from Europe.

Arrivals from Italy are subjected in Austro-Hungarian ports to ten days' quarantine if free from sickness, or to twenty days or more in contrary cases.

Arrivals at Algiers from all French and foreign ports in the Mediterranean, comprising Gibraltar and Tangiers, except Algeria and Tunis, will be subject to a quarantine of seven full days. Vessels having been seven days at sea without putting into port will be subject, on their arrival at Algeria, to a simple quarantine of observation of one day to three days.

Vessels arriving at Spanish ports direct from Newfoundland (their original starting-point not being France) are subject, if with clean bills of health, to three days' observation in the port of discharge.

At St. Thomas arrivals from North Africa have to undergo quarantine, as also have ships arriving from English and French Windward Islands which have direct or indirect communication by steamers with Europe.

The period of duration for quarantine for vessels leaving the Italian peninsula for the islands of Sicily, Sardinia, and other adjacent islands has been raised to twenty-one days.

Arrivals in Roumania from French Mediterranean or Italian ports have to perform quarantine at Soulina or Kustenje.

At Constantinople the ten days' quarantine on arrivals from the Black Sea has not been enforced. At Kavak passenger vessels undergo five days' quarantine.

Quarantine is applied to vessels arriving at the islands of Sicily and Sardinia from the French ports in the Mediterranean, Algeria, and the Regency of Tunis.

At Dunkirk all vessels from Italian ports undergo twenty-four hours' observation.

Vessels from Spezia are subject in other ports of Italy to a preventive observation of ten days.

At Odessa all vessels from Italy are to undergo fourteen days' quarantine, irrespective of that which may have been performed at other ports *en route*.

All vessels arriving in Norway from Belgium, Holland, and German North Sea ports must undergo medical examination before being allowed to communicate with the shore.

The quarantine regulations applying to Sicily and Sardinia apply also to the island of Elba.

At the Hague all the French ports in the Mediterranean, as well as the Italian ports extending from the French frontier as far as and including Civita Vecchia, have been declared to be infected with cholera.

At New Orleans the period of quarantine will, from and after Sept. 15th, be reduced from forty to ten days.

Vessels proceeding from cholera-infected ports and arriving at Monte Video and Buenos Ayres, after being less than forty days at sea, will be absolutely excluded from these ports as long as cholera shall continue to show itself at the place of departure.

All persons arriving in Russia from France and Italy must be provided with certificates from Russian consular officers, that they have not been at any of the infected localities within three weeks of their departure for Russia.

DISUSED BURIAL-GROUNDS.—The disused burial-ground surrounding the parish church in Upper-street, Islington, is to be converted into a public recreation ground, at an estimated cost of £1100, half of which will be defrayed by the Metropolitan Board of Works, and the other moiety by the vestry of Islington. The space, an acre and a half, is to be well turfed and provided with a few flower beds.

REPORT OF THE ROYAL COMMISSION ON PRISONS IN IRELAND.

IN our issue of August 23rd we briefly alluded to the above, but the text requires more than a passing notice, as it involves charges in the administration of a comprehensive character. Passing over the first part of the report, as not directly affecting the medical treatment of prisoners, we come to the 56th paragraph, where the status of gaol surgeons is laid down. We notice that the commissioners have apparently failed to realise that at present there are actually three classes of medical officers—viz., (1) those appointed before 1877, who are surgeons to their respective county infirmaries; (2) those who were likewise appointed previous to the passing of the Prisons Act, but are not infirmary surgeons; (3) those appointed by the Lord Lieutenant since the passing of the Act. The tenure of office of the first two classes was explicitly laid down in the 27th section of the Prisons Act, and it will be within the remembrance of our readers that the ill-advised action of the chairman of the General Prisons Board in issuing a circular on May 3rd, 1879, stating that their tenure of office ceased to exist after the passing of the Prisons Act, occasioned a rupture with the several medical officers, necessitating on their part joint action, and even requiring them to threaten legal proceedings in case their status should be questioned. We regret therefore to find that this point has been not fully taken into consideration, as evidenced by the few introductory words of the 56th paragraph. After paying a well-deserved compliment to their general character, the paragraph states that the commissioners report that there is considerable friction between the medical officers and "the board." If by "the board" the commissioners allude to the chairman, we unhesitatingly accept the dictum; but between the medical officers and the vice-chairman and Mr. O'Brien (the third member) there has not been any friction; and we go further, and state that at no time was there the slightest friction between the late chairman, Sir W. Crofton, or the present hon. member, Sir J. Lentaigne. When a body of men holding the social and professional status in their respective counties, such as the existing medical officers of prisons, are coolly informed that their offices are vacant, when subsequently to this they are treated with persistent discourtesy, when their suggestions are ignored, and their duties as defined by Act of Parliament altered to suit the caprice of one person, a certain amount of friction must ensue. As we stated in an article (Dec. 8th) on the Royal Commission: "The board failed to conciliate their medical officers"; and further on, "their failure to effect this may rest to a great extent on the *personnel* of the board." The report of the commission throws new light on this "friction," for, as we read at paragraph 29, "it is in evidence that there has been for some time an entire suspension of communication, except in writing, between the chairman of the board and the inspector of his district." The inspector alluded to is remarkable for his efficiency and courtesy.

Paragraph 52 deals with the "friction" with Mr. Mac G. Eager, the governor of Limerick prison, in which case the Lord Lieutenant had actually to reverse the mandate of the board. We are aware of instances in which the chairman when inspector-general of prisons had very considerable "friction" with gaol boards of superintendence, and it is even now generally considered that there has been "friction" between the chairman and another member of the board. In paragraph 29 the report states "that upon the evidence before us it may well be questioned whether some of the principal authorities of the Irish Prison Service manifest towards one another that spirit of cordial co-operation which always contributes so much to the successful working of a public department." This indicates where the commissioners were of opinion the friction lay, and we regret that they did not apportion their blame in an honest and straightforward manner.

In February, 1883, the honorary secretary of the Association of Gaol Surgeons in Ireland forwarded, at the request of Sir R. Cross, an exhaustive statement to the commission, dealing with many points in connexion with the subject, amongst others, the daily visits to prisoners on extra diet ordered by the chairman, the rule requiring their attendance before twelve o'clock, the refusal of the board to supply them with the ordinary instruments necessary for

Digitized by Google

their duty, the unnecessary number of books to be kept, the non-payment of substitutes in case of illness or absence on public duty, the necessity for the appointment of hospital warders, and the objection to warders' families living in the prison. We are glad to see that in paragraphs 58, 60, 61, 62, 64, 65, and 72 the justice of these complaints has been acknowledged and their recommendations adopted. All these points we indicated in our issue of November 17th, 1883. We cannot leave this part of the report without drawing attention to a portion of paragraph 59, in which the board are convicted of a deliberate attempt to falsify a report. The circumstances are shortly as follows:—A medical officer was called on to attend a member of a warder's family who resided in the town. This duty he objected to perform, as not being laid down in his instructions or implied by usage. A correspondence with the board ensued, and in their minute of August 23rd, 1880, they state, "That the Prisons Board '*require*' the medical officer to attend the families of warders, provided they live within one half mile of the prison; and the medical officer neglecting to do so acts thus at his peril, and it is the duty of the governor to report such omission of duty." The discharge of this duty by medical officers of prisons "was one of the reasons put forth by the late departmental committee entitling medical officers of prisons to an increase of salary." Paragraph 59 states: "We do not find that the performance of this duty was stipulated for when the salaries of the medical officers were last fixed, although it was so stated to them by the General Prisons Board." It is inconceivable how any board could make such a mis-statement, or, having made it, be allowed to retain their places.

The report deals very particularly with the control and inspection of the various convict establishments in Ireland, and in paragraph 119 with the intermediate prison at Lusk. We think they are wise in recommending its discontinuance; they find that it is both useless and expensive. It may be that the distinctive character of Lusk—namely, the careful selection of its inmates—has been carried out too minutely. There were only twenty-four convicts there at the time the commissioners inspected it, and the cost of maintenance and staff combined reached the exorbitant sum of £36 per head. This is out of all proportion to any result obtainable.

We are glad to find that the report recommends the personal inspection of all convict establishments by the members of the board instead of the inspectors.

The diminution of the number of prisons in Ireland is also recommended, and we agree with the commissioners that the grouping together, as in England, of large numbers of prisoners is conducive to greater economy and efficiency, both in maintenance and treatment. Under the present system each prison has only a relatively small number of prisoners; as a consequence a large proportion are employed as warders, cooks, cleaners, &c., which interferes with the task labour, trades, and education carried on. By consolidating the prison administration greater economy can be practised, better educational and labour results obtained, and a healthier *morale* initiated.

Space prevents our going into the report at greater length; it is in many respects a valuable addition to our knowledge of prison affairs in Ireland, and is the result of the protracted labour of an essentially able commission. They recommend changes in the board which we advocated last year, and which anyone cognisant with prison affairs in Ireland was satisfied must eventually be decided on.

We congratulate our medical *confrères* especially, as to them is largely due the beneficial changes in contemplation. Drs. Robert MacDonnell and Sigerson devoted much and valuable time to the question, and the interests of the medical officers were safe in their hands. The proceedings of the commission were conducted with thoroughness and tact, and we hope the result to the general administration and the medical officers will be the establishment of harmony and general co-operation the absence of which the report so much deplores.

WESTMINSTER HOSPITAL.—The Committee of Management of this hospital have decided upon a scheme to extend the accommodation for out-patients, the resident medical staff, and the nurses. The plan includes the erection of a new medical school apart from the hospital building. The estimated cost of the improvements is £18,000, £5000 of which has already been subscribed.

FRENCH HEALTH RESORTS.

(From our Paris Correspondent.)

ROYAT; MONT DORE.

THE waters of Royat, a pretty little town situated in a valley about half a mile from Clermont-Ferrand, are chloro-alkaline, lithic, and ferro-arsenical, which, according to the different sources they are taken from, are considered useful in a variety of affections, such as those comprised under the term arthritism (gout, rheumatism, eczema, &c.), and in chloro-anæmic and nervous ailments. They have also been found highly useful in uterine diseases, the successful treatment of which has obtained for Royat the title of the French Ems. Affections of the throat and lungs are also much benefited by these waters. They are gaseous, containing certain proportions of free carbonic acid, and of varied temperature. They are employed internally and externally. Their action in the economy is similar to that of the pure alkaline waters, without having any of the inconveniences of the latter, owing to their containing a large proportion of chloride salts and to the presence of iron and arsenic. The "Source César" is the most popular, and is more freely drunk with wine at the table than the water from the other springs. It is slightly stimulant and tonic, owing to the carbonic acid with which it is saturated. Taken in health, it has the effect of stimulating the mucous membrane of the stomach, develops the appetite, and considerably increases the urinary secretion. Taken at meals and mixed with wine, it facilitates digestion and relieves nausea when present. Its use is particularly recommended to persons of sedentary habits, and to those having much mental labour to perform; also to constitutions weakened by hard physical work, disease, &c. The bathing and hydrotherapic arrangements are most complete, there being a large swimming bath containing running water naturally tepid at 31° to 32° C., and suitable for patients of all ages. Dr. Boucomont, one of the principal physicians and inspector of the waters at Royat, showed me an apparatus of his own invention, by which a patient who cannot stand the shock of a cold douche has only his feet douched, without wetting the upper parts of his body. He has found this very useful in nervous patients, particularly those of the female sex, and in all cases of congestion of any of the viscera, even of the brain, which may be benefited by derivation towards the lower extremities. It struck me that such a mode of applying the douche would be useful in insomnia, but Dr. Boucomont said he had not yet tried it in such cases. But, besides invalids, tourists will find here sufficient opportunity to satisfy their scientific curiosity, whether it be in natural history, archæology, mineralogy, or numismatics. The same may be said, indeed, of the whole of Auvergne, which is laid out in charming landscapes, picturesque scenery, and a soil most varied in character. The range of volcanic mountains of this beautiful province, its druidical remains, its Byzantine churches, its mediæval castles, its pine woods, its cascades, and its torrents, all contribute to captivate the attention of the tourist. Royat is evidently a rising place, and deserves to be better known; but it is impossible for me, within the limits of a letter, to do more than scant justice to a health resort that possesses so many advantages over similar places in this or any other country. Anyone interested in this watering place cannot do better than read a description of it in a little work by Dr. Boucomont, entitled "Les Eaux Minérales d'Auvergne," which of course contains information only from a medical point of view. The season begins about the middle of June and ends about the middle of September, the cure lasting about three weeks. The treatment should be continued for some time on the return home of the patients by drinking the bottled waters. Those from the César and St. Victor springs should be preferred for this purpose, as they are of a lower temperature, and are on that account, and from their containing a large proportion of free carbonic acid, better kept in a state of preservation than the water of the other springs, of which there are two: "La Grande Source," or what used to be called the "Source Eugénie," and the "St. Mart." They are particularly adapted to gouty and rheumatic subjects in the chronic or asthenic forms, who, being unable to visit the spa itself, are obliged to drink such waters for an indefinite period. They are also found particularly useful in the cutaneous manifestations connected with these diatheses.

On leaving Royat, I proceeded to Mont Dore, which is

Digitized by Google

situated about the middle of a valley surrounded by high mountains—the Capuchin, the Angle, and the Pic de Sancy, the last (the highest) being 6186 feet above the level of the sea. A vegetation of the deepest green covers the two sides of the valley, and the shades are lovely. Two cascades, the Dore and the Dogne, unite to form the Dordogne, whose limpid waters overflow the meadows at the foot of the valley. Mont Dore, which is in the department of the Puy-de-Dôme, is thirty miles to the west of Clermont, and is reached partly by railway and partly by an engineering road in diligences and carriages, winding up and across a charming country, which for beauty and grandeur may be compared to Switzerland. Its altitude is about 1050 metres, or about 3445 feet, above the level of the sea. Its climate is rather mild, the thermometer seldom rising above 86° F. in the two hottest months of the year (July and August), and rarely falling below 40° F. It is, after Barèges, the highest watering-place in France, and therefore favourable to debilitated subjects, and to those who cannot resist the heat of the plains. Notwithstanding what has been said and written to the contrary, I should consider it quite unsuited for phthisical patients in any stage of the disease, owing to the great fall of the temperature in the evenings, which are damp; yet invalids are to be found there in large numbers. Mont Dore is certainly one of the most ancient, if not the most important, thermal stations of France, having been known as such almost since the commencement of the Christian era; it was also much frequented by the Gauls and Romans, who had constructed there a vast establishment, as shown by fragments of columns and the ruins of a swimming bath, which may be seen at the present day. The waters of Mont Dore, which are the least mineralised of all the waters of Auvergne, have been classed among the alkaline bicarbonates. They contain chloride of sodium and sulphate of soda, with mere traces of iron and alumina. They also contain a small quantity of arsenic (about a milligramme to the litre), the presence of which latter would seem to justify their employment in pulmonary phthisis. The waters from the various springs, of which there are no less than seven, are hot, their temperature rising as high as 109° F. They all contain the same ingredients, varying only in quantity according to the different springs. Mont Dore is celebrated for its various kinds of baths, and its rooms for spray and inhalation. Herein the patients breathe the mineral waters reduced to steam; but I question the propriety of applying this treatment to phthisical patients, not only on account of its weakening powers, but of the known tendency of such treatment to produce congestion of the lungs, and thus determine spitting of blood. If Koch's theory as to the propagation of pulmonary tuberculosis by bacilli emanating from the lungs of phthisical patients be correct, there is here offered a favourable field for their dissemination through the atmosphere of these rooms (eight in number), which are small, communicating with steam boilers, and in which there are ten or twelve patients at a time divested of their ordinary clothes and dressed in a flannel costume made for the purpose. Here they breathe the same vapour with which the room is filled, and here they remain from fifteen to forty-five minutes, or as long as they can conveniently bear it. Moreover, the patients must run the risk of catching cold on leaving the "sudatorium," as it has been appropriately termed, although every precaution is taken against their doing so. According to the physicians practising at Mont Dore, the waters of this spa have been found most useful in all affections of the respiratory organs, including asthma and pulmonary phthisis, also in chronic rheumatism, gout, and congestion of the liver. Nasal catarrh with ozæna, of whatever origin, is successfully treated by the use of these waters, administered internally, but more especially by local irrigation with them. The latter is effected by the use of an indiarubber tube, but the operation must be performed with caution, and under the surveillance of a medical man, as headaches and even syncope have been induced by the water penetrating the frontal sinuses. Like all watering-places in France, Mont Dore is provided with the inevitable casino, which is composed of a theatre, ball-room, reading-room, rooms for billiards and other games, and for refreshments. It is not much frequented by foreigners, and this may account for the hotel accommodation not being equal to that obtained in the other stations, where the comfort of visitors, particularly English and American, is more studied. The season begins about the middle of June, and ends about the same time in September; but July and August are the months most favourable for following the course of treatment enjoined at Mont Dore. The waters should not be used for more than a fortnight on account of their exciting properties, and the local physicians should always be consulted in the matter. I may, however, observe that the waters are contra-indicated in persons of a languid circulation, and such as have a tendency to hæmorrhage.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Peterborough (Rural).—This district had in 1883 a death-rate of 17·3 and a birth-rate of 30·5 per 1000 living. Diphtheria was somewhat prevalent in the district, and, as so often happens, it exhibited a certain obscure relationship with scarlet fever. Speaking generally of the class of infectious diseases due to filth causes, Dr. Paley observes that the district has been comparatively free from them, a result which he attributes to the efficient removal of all sorts of filth accumulations from the vicinity of the dwellings of rich and poor alike.

Hendon (Urban).—Dr. Cameron gives a lengthened account of the continued prevalence of diphtheria and scarlet fever, which were so marked during the first nine months of 1883, and to which we at the time adverted, especially in connexion with Mr. Power's report on an earlier stage of the outbreak. On the whole, the general health of the district was much better at the end of 1883 than at the end of the previous year, and a hope is expressed in the report that the experiences of 1883 will prove to be exceptional in the history of the district. Seldom have recurrences of diphtheria proved so persistent, and this notwithstanding efforts made to prevent the diffusion of the disease by means of intercommunication. Estimating the population at 11,370, the death-rate was, considering the circumstances, remarkably low—namely, 15·7 per 1000. Hendon at last stands a chance of being efficiently sewered; the scheme has been submitted to and approved by the Local Government Board, and the work is, we trust, now in progress.

Rotherham (Urban).—This borough, with an estimated population of 35,650, had in 1883 a death-rate of 20·5 per 1000, this rate exhibiting a decrease not only on that of the previous year, but also on the annual average for the preceding ten years. Zymotic diseases were also less prevalent than formerly; but this is certainly not due to the completeness of the provision for arresting the progress of those affections which can properly be called infectious, for the borough is still unprovided with either an infectious hospital or a mortuary. Smoke is still a cause of much trouble to the town, it being deluged with carbon and deleterious gases, resulting from the wasteful methods of combustion which are in vogue. Substantial additions have been made to the work of sewering the borough, and a number of street improvements have been effected. But efficient sanitary regulation in connexion with bye-laws and the cattle market still calls for the attention of the authority.

South Shields (Urban).—South Shields, with a population of some 62,000, may be congratulated on having achieved a substantial reduction in its annual mortality. The rate per 1000 for 1883 stood at 20·9, but taking the means of triennial periods, Dr. Munro claims to show clearly the sanitary progress which has been effected. For the three years 1872–74 the rate was 25·8; that for the years 1875–7 was 22·7; that for 1878–80 was 22·6; and during the past three years the mean has stood at 19·7. This, too, is accompanied by a fall in the rate of infant mortality, the deaths under one year now standing at 13·9 per 100 registered births, as opposed to 14·9 in the fifty large towns. So also the rate for the so-called zymotic diseases was 2·27 per 1000, whereas in the fifty towns it was 2·46. The most important incident in the sanitary history of the year was the opening of the new borough infectious hospital, an establishment well adapted to the needs of the district, and subject to an excellent system of administrative regulations. During the year fifty-one patients came into the building, twenty-three of these being cases of scarlet fever, twelve of small-pox, seven of

Digitized by Google

typhoid, three of typhus, &c. Taking all the cases together the mortality was only at the rate of 1 in 17. The new facilities which the hospital affords of safely receiving at one and the same time cases of the different infectious fevers, and the comforts and prospects of recovery which it provides, are certain to make it a real sanitary success. Dr. Munro feels very strongly that one of the most potent instruments he can use in securing improved sanitation is to teach the people how to help themselves in the matters that concern health, and he has commenced work in this direction by organising a working class for women at which elementary lessons in physiology, nursing, the maintenance of healthy homes, and the management of infectious diseases have been given. The effort is certain to be successful if it is sustained, and it is to be hoped that it will receive support in the district. In the meantime, the current sanitary work not only goes on but steadily increases.

Sunderland (*Urban*).—This borough had in 1883 an estimated population of 121,117, the density per acre being 41·5. The births were at the rate of 41·7 and the deaths at 24·4 per 1000 living. But during the third quarter of the year the Victoria Hall catastrophe occurred, by which 178 little children lost their lives, and if these deaths are deducted the rate is reduced to 21·3. The relative mortality of infants under one year was at the rate of 137·8 per 1000 registered births, the lowest rate without exception in the twenty-eight large towns of the kingdom. The deaths from the diseases included by the Registrar-General under the term of principal zymotic were lower than in any of the preceding ten years—namely, 2·55 per 1000 inhabitants, and this notwithstanding a severe prevalence of typhus in the early part of the year and of the continued presence of small-pox in the third and fourth quarters. In all, small-pox caused 52 deaths and typhus 41. We have before commented on these two epidemics in connexion with the means of isolation that are available in the borough—namely, an old private residence utterly unfitted for the present purposes, and the infectious buildings at the workhouse. Against both these buildings, it is admitted, there exists great prejudice in the mind of the public, and deservedly so, for it is risky to go into the one lest the sufferer should contract a second disease, and it is degrading from a social point of view to go into the other. The number actually isolated was higher than in any previous year, 113 being removed to the borough House of Recovery and 180 to the Union Hospital. Amongst those thus removed 216 were small-pox patients. Compulsory measures of removal were not resorted to, and this because, as Mr. Harris admits, he would otherwise have made people paupers against their wish. How far this is reconcilable with the statement which immediately follows, to the effect that "very strong persuasive pressure was put on patients to avail themselves of hospital shelter," it is not for us to explain; but most people know that the power that can be obtained over persons lying helpless in sickness is one that also carries with it a considerable responsibility as to the rights and interests of the individual on whom it is brought to bear. Mr. Harris, however, certainly had the best interests of his borough at heart, and it is to be hoped that the episodes of the past twelve months will result in Sunderland being provided with a proper hospital to which patients can be sent in the interests of the health of their fellow citizens, without their being subjected to such risk or social degradation as cannot reasonably be demanded of them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 30th ult., 5618 births and [illegible] deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had been 24·1 and 25·4 in the two preceding weeks, declined last week to 25·3. During the first nine weeks of the current quarter the death-rate in these towns averaged 23·4 per 1000, against 20·7 and 20·0 in the corresponding periods of 1883 and 1882. The lowest rates last week in these towns were 19·6 in Birkenhead, 19·7 in Derby, 19·9 in Bristol, and 20·0 in London. The rates ranged upwards in the other towns to 34·1 in Manchester, 35·4 in Blackburn, 37·5 in Halifax, and 37·8 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 911, 1106, and 1214 in the three preceding weeks, declined last week to 1203, [illegible] diarrhœa, 70 from scarlet fever, 69 from whooping-cough, 64 from measles, 52 from "fever" (principally enteric), 23 from diphtheria, and 15 from small-pox. These diseases caused the lowest death-rates in Derby, Bristol, and Plymouth, and the highest in Wolverhampton, Blackburn, and Preston. The highest rates of mortality from diarrhœa were recorded in Hull, Wolverhampton, and Preston; from measles in Halifax and Bolton; from scarlet fever in Leeds and Cardiff; and from whooping-cough in Sunderland. The 23 deaths from diphtheria in the twenty-eight towns included 16 in London and 2 in Portsmouth. Small-pox caused [illegible] deaths in London, 1 in Liverpool, 1 in Sheffield, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which in the seven preceding weeks had declined from 1368 to 587, further fell to 539 on Saturday last; the new cases admitted were 63, against 110, 64, and 53 in the three previous weeks. The Highgate Small-pox Hospital contained 20 patients on Saturday last, 4 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which in the four preceding weeks had declined from 196 to 157, rose last week to 181, and were 12 above the average. The causes of 103, or 2·4 per cent., of the 4245 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Norwich, Newcastle-upon-Tyne, and in three smaller towns. The largest proportions of uncertified deaths were recorded in Preston, Salford, Bolton, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the two preceding weeks had been 20·7 and 20·8 per 1000, declined to 20·8 in the week ending the 30th ult., when it was 4·5 below the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 15·0 in Perth and 15·1 in Aberdeen, to 22·8 in Dundee and 24·9 in Glasgow. The 503 deaths in the Scotch towns included 68 which were referred to diarrhœal diseases, 27 to whooping-cough, 6 to scarlet fever, 8 to diphtheria, 6 to measles, 4 to "fever," and not one to small-pox; in all, 121 deaths resulted from these principal zymotic diseases, against 109 and 111 in the two preceding weeks. These 121 deaths were equal to an annual rate of 5·0 per 1000, which was 2·6 below the average rate from the same diseases last week in the twenty-eight English towns. The deaths referred to diarrhœa, which in the two previous weeks had been 51 and 74, declined last week to 68, but were double the number in the corresponding week of last year; 36 occurred in Glasgow and 10 in Dundee. The 27 fatal cases of whooping-cough showed a further slight decline from recent weekly numbers, and included 11 in Glasgow, 5 in Edinburgh, and 5 in Aberdeen. Of the 8 deaths from scarlet fever, which were 6 less than the number in the previous week, 7 occurred in Glasgow. The 8 fatal cases of diphtheria also showed a decline, and included 5 in Glasgow and 2 in Edinburgh. The 6 deaths referred to measles corresponded with the number in the preceding week, and of the 4 fatal cases of "fever" 3 occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed but slightly from those returned in recent weeks, and corresponded with the number in the same week of last year. The causes of 83, or more than 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been in the three previous weeks from 22·4 to 30·3 per 1000, declined to 29·9 in the week ending the 30th ult. During the first nine weeks of the current quarter the death-rate in the city averaged 23·8 per 1000, the rate during the same period being 22·4 in London and 16·7 in Edinburgh. The 227 deaths in Dublin last week were within 3 of the high number in the preceding week, and included 65 which were referred to the principal zymotic diseases, against numbers steadily increasing from 16 to 45 in the five preceding weeks. Of these, 48 resulted from diarrhœal diseases, 9 from scarlet fever, 4 from whooping-cough, 3 from "fever," 1 from diphtheria, and not one either from small-pox or measles. The 65 deaths were equal to an annual rate of 9·7 per 1000, a rate from the same diseases not exceeding 4·4 in London

Digitized by Google

3·6 in Edinburgh. The fatal cases of diarrhœa, which had been 8, 22, and 25 in the three previous weeks, further rose to 48 last week. The 9 deaths from scarlet fever showed a decline of 4 from the high number in the preceding week. The fatal cases of whooping-cough showed a slight further increase upon recent weekly numbers, while those of "fever" corresponded with the number in the previous week. Four inquest cases and four deaths from violence were registered in the city during last week, and 34 deaths occurred in public institutions. The deaths of infants showed a further increase upon those returned in recent weeks, while those of elderly persons showed a decline. The causes of 39, or nearly 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General Francis Holton, M.B., retires on temporary half-pay; Surgeon-Major Joseph Bourke, late Medical Department, has been permitted to commute his retired pay.

ADMIRALTY.—Fleet Surgeon William Shute Fisher, B.A., M.B., has been placed on the retired list, with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets; Staff Surgeon John Buckley has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

The following appointments have been made:—Surgeons George W. Low, Charles W. Hamilton, and Henry Harries, to the *Alexandria;* Surgeon Albert P. Wells to be Surgeon and Agent at Douglas, Isle of Man; Surgeon J. Chaque, to be Surgeon and Agent at Castletown, Isle of Man; Staff Surgeon Hugh H. Hannay, to the *Britannia;* Staff Surgeon Heaver Sugden, to the *Hector;* Surgeon Edward Ferguson, to the *Rapid;* Surgeon John Ottley, to the *Vernon;* and Surgeon William H. O'Meara, to the *Repulse.*

Correspondence.

"Audi alteram partem."

TREATMENT OF ASIATIC CHOLERA.

To the Editor of THE LANCET.

SIR,—Notwithstanding the rapid and effective strides which sanitary science has made and is making, and the manner in which it is being applied to stay the progress of the common enemy cholera, it appears to me that the medicinal treatment of this disease, whether prophylactic or curative, is uncertain, and that the writers upon the subject in the medical press touch upon the subject in a delicate manner. If a number of professional men were asked what their treatment would be, their replies, I think, would vary in form, and would be contradictory. We have to deal with (1) a zymotic disease; (2) a disease where everything is rejected by vomiting, and (3) a disease in which rapid collapse takes place.

Treatment.—Put the patient to bed. Inject hypodermically a solution of carbolic acid (half a grain of crystallised carbolic acid in twenty drops of water) with a solution of hydrochlorate of morphia, which may be repeated at intervals, as necessary. Let him have a hot-air bath made with a lamp and cradle over the bed, or hot bricks wrapped in flannel, and applied to the soles of the feet and armpits. Let him sip freely and frequently of sulphurous acid lemonade with glycerine, of which the following is the formula: Sulphurous acid, one ounce; glycerine, three ounces; tincture of lemon, four drachms; syrup to eight ounces. Half an ounce mixed in a tumbler of water makes "sulphurous acid lemonade."

Diet.—Let his diet be composed solely of white of egg well beaten up, and mixed with an equal quantity of water, and given cool in small quantities frequently.

External treatment.—The patient to be sponged occasionally with hot solution of carbolic acid (as in small-pox, to protect the patient as well as the nurse). All soiled linen coming from the patient to be put into a like solution.

During an epidemic of cholera something important also may be done in the prophylactic way, by the administration of such medicines as will, we know, act as bactericidal anti-zymotics. An ingenious plan was adopted during a former epidemic by my friend, Dr. Jas. Arthur Power, by means of which all our households took anti-zymotic medicine inadvertently; the plan was the mixture of powdered hyposulphite of soda with ordinary table salt, in the proportion of a small teaspoonful to an ordinary salt-cellarful; thus a good anti-zymotic was administered daily in a tasteless form. A pill containing half a drop of creasote taken with meals is an excellent anti-zymotic remedy. All drinking water should be boiled and filtered and allowed to cool.

I am, Sir, your obedient servant,

Sydenham, August, 1884. F. EACHUS WILKINSON, M.D.

THE "METAPHYSICS" OF COMTE.

To the Editor of THE LANCET.

SIR,—Knowing something of the writings of Auguste Comte, and being well acquainted with the distinguished group of men who are the propagandists of his doctrines in this country, I am completely at a loss to understand what Dr. Moxon means by his allusion to the "most rubbishy metaphysics of Comte." It would, indeed, be hardly possible to devise a more incongruous phrase, for that great thinker claimed before all things to be the prophet and apostle of positive science; and if there be one feature of his system more distinctive than another, it is its complete divergence from, and antagonism to, metaphysical speculation. "The big, merciless hand," which Dr. Moxon deprecates as an attribute of our profession, may be wielded by the critic to malign the great as well as to crush the small, but the least we can look for is the exercise of some discretion in its use. It is the fate of Comte's philosophy to meet with assiduous misrepresentation; but no one who had ever read a line of Littré, of John Stuart Mill, of Buckle, or of G. H. Lewes, could fall into the ludicrous error of taunting it with being metaphysical. Indeed, it is not necessary to go beyond your own pages for the complete refutation of such an idea, which will be found well expressed in Dr. Walshe's able and scholarly papers on "Physiology *v.* Metaphysics in Relation to Mind," published in THE LANCET of this year.

I remain, Sir, your obedient servant,

Sussex-gardens, Hyde-park, Sept. 1st, 1884. T. FITZPATRICK.

VACCINE.

To the Editor of THE LANCET.

SIR,—I observe in your annotation of July 5th on "Vaccination in the Metropolis," you remark that arm-to-arm vaccination is "far more protective" than any other. I would respectfully ask if statistics are available to confirm this statement, for it has always seemed to me that a successful vaccination exhibiting the Jennerian vesicles is all that can be desired, let the source of the virus be human or bovine, tube, point or crust. If your position is the correct one, we have the curious spectacle of a human vaccinifer furnishing the ideal vaccine, without himself or herself having the best protection. In Canada the human crust is much used.

I am, Sir, yours truly,

Montreal, August 4th, 1884. T. D. REED, M.D.

*** Our words were, "arm-to-arm vaccination is far more protective than the use of stored lymph, whether it be human or animal." The reason for this statement is that vaccination with stored lymph "takes" with much less certainty, and often produces much smaller vesicles than vaccination done directly from arm to arm. See also the report of the medical officer to the Local Government Board for the year 1882, article, "The Animal Vaccine Establishment."—ED. L.

HOSPITALS FOR INFECTIOUS DISEASES.

To the Editor of THE LANCET.

SIR,—On my return from the seaside I saw the article on this subject by Dr. Wilson in your journal, in which he refers to a paper of mine read at the Society of Medical Officers of Health, and published (in part) in a medical contemporary. As the whole of the part referring to the "spot maps" I have made was left out in that abstract,

Digitized by Google

the evidence on which my statements were based is necessarily incomplete; otherwise I think Dr. Wilson would have come to another conclusion. He also observes that I said that the line of direction of alleged infection was against the wind. This is an error, as I said it should have been E.N.E. instead of S.E. and E.S.E., but that the wind probably veered a little without being noticed, as I note the direction only once a day.

I am, Sir, yours faithfully,

JOHN W. TRIPE, M.D.,

August 30th, 1884. Medical Officer of Health for Hackney.

NEWCASTLE-ON-TYNE.

(From our own Corresponden.t)

PROPOSED TESTIMONIAL TO THE MAYOR OF NEWCASTLE-ON-TYNE.

THERE was an important gathering of citizens in our Council Chamber on Friday last for the purpose of furthering the movement to present the mayor, Mr. H. W. Newton, surgeon, with a testimonial in recognition of his services in connexion with the recent Royal visit to Newcastle. The chair was taken by Mr. T. L. Gregson (our deputy mayor), an old and respected member of our profession, who made a graceful speech, in which he observed that he thought it would be discreditable if, after the admirable manner in which Newcastle had vindicated its loyalty, they did not recognise in a fitting manner the way in which the mayor had so successfully carried out all the proceedings in connexion with the recent Royal visit. He had seen himself several Royal receptions, but none in which hearty loyalty was so thoroughly accompanied by good order, excellent feeling, and sobriety as that of Newcastle. No doubt much of the work in connexion with the event had to be done by other people, but the crowning success was due to the exertions of the mayor in uniting all into the one effort of making the occasion of the visit a success. On the conclusion of the address a subscription list was opened, and about two hundred guineas were received. It is felt here, in the profession and outside of it, that our worthy mayor well deserves this recognition of his kind and intelligent attention to the wants and comforts of all classes of our citizens on the occasion.

THE DEATH FROM ENGLISH CHOLERA AT ALNWICK.

The Board of Health at Alnwick have had a special meeting in reference to the fatal case commented upon in your issue of last week. Some members have taken the coroner to task for sending a copy of the depositions to the Local Government Board; some are also severe on the medical officer of health for giving his evidence; but, so far, THE LANCET has escaped. One of the members stated that he had been informed that the man previous to his death had eaten fourteen fresh herrings and drunk two quarts of beer with a quantity of cabbage-water for a wager; be this as it may, the Local Government Board have taken the matter up, and have written to say that they have instructed their inspector, Dr. Spear, to visit the district at an early date and to inquire into its general condition.

SUNDERLAND INFIRMARY.

The past year, it appears, has witnessed the largest number of in-patients the institution has ever received, no less than 1482 having been treated. The average number of patients resident in the house daily has advanced from 104·1 in 1882–83 to 119·4 in 1883–84. The death-rate has been reduced from 3·8 per cent., as against 4·3 per cent. in the preceding year; and 70 per cent. of the patients have been cured. There were 231 patients in the children's wards during the year, and it is satisfactory to note that these wards are affording so much relief to the little sufferers of the town and neighbourhood. A very important point deserves full notice in connexion with Sunderland Infirmary; it is that the workmen's subscriptions from the various collieries &c. in the neighbourhood form the most important item in the income of the institution. The expenditure connected with the building, fitting up, and furnishing of the new wing of this very fine infirmary amounts to nearly £11,000, on which there is a debt, but not a very heavy one.

Newcastle-on-Tyne, Sept. 1st, 1884.

CANADA.

(From a Correspondent.)

THE COUNCIL OF THE COLLEGE OF PHYSICIANS AND SURGEONS, ONTARIO.

IT is confidently expected that this body is about to take some definite steps in the direction of securing power from the Legislature to deal in a severe and peremptory manner with a class of men who, after having obtained a medical diploma, prostitute themselves and their profession by engaging in a disreputable kind of practice, or by actually hiring themselves out to some daring adventurer who seeks to drive a good business by every possible form of advertising. To reason with such persons is utterly useless, as they have cast to the winds every rule of ethics which might be supposed to have any hold upon the members of the healing art. It is really to be hoped that the coming session of the Legislature will confer upon the College the power to remove from the Register the names of all who may engage in any such nefarious kind of practice.

CHOLERA PRECAUTIONS.

Although there is not much excitement regarding the prospects of a visit from this dreaded disease, very useful measures are being enacted. The larger cities are stirred up to a careful inspection of their sanitary condition. Dwellings and out-houses are being examined, all filth removed, and the streets and sewers well cleansed. In the maritime provinces, a quarantine has been ordered for all vessels from Marseilles and other suspected ports. The Ontario Board of Health is doing useful work by scattering information among the people, and inducing the smaller towns to put their houses in order.

A NEW MEDICAL SCHOOL.

It is now a certainty that there is to be a medical college in Winnipeg. Of course the North-western part of the Dominion is very vast as far as territory is concerned; but the number of practising physicians in it is not very great. The opportunities for clinical teaching in Winnipeg cannot be as good as in some of the more easterly and larger cities. Manitoba, however, is increasing rapidly in population, and there may be a useful and bright future before the young college. It is to be in affiliation with the University of Manitoba, which has instituted a very creditably high standard for the entrance examination.

HIGH-PRESSURE IN SCHOOLS.

At the Ontario Teachers' Association meeting the other day, Principal Grant, of Kingston, made a strong appeal against the system of too extensive a curriculum of study for young children. He took the ground that to ask too much from a child was to fail in getting any good work done. The mind, crowded with too many subjects, had not the time necessary for accurate study; while the habit of doing loose, imperfect work had a bad effect on the young mind, and was not education at all.

THE BRITISH ASSOCIATION.

It is certainly a noteworthy event to see this distinguished Association assembling in a city three thousand miles distant from York, where it held its first meeting in 1831. Mr. Phillips, a secretary of the Yorkshire Philosophical Society, acting on a suggestion in a letter to him from Sir David Brewster, issued invitations to the leading science men of Britain, and out of the meeting thus summoned has grown the present Association. Canada was but little thought of then, and was perhaps regarded as a wild woodland, the fitting home of the Red Indian. Many of the members of the Association intend to give the country a general visit, while quite a number have taken tickets for the Rocky Mountains and other points in the "far West."

August 15th, 1884.

THE RED CROSS ASSOCIATION.—The members of this Association, to the number of about 100, assembled at Geneva, on Monday last, this being its third international convention. The president is M. Moynier; the three hon. presidents are Professor Lehmore, Professor von Langenbeck, and Count Sérurier; and Mr. John Farley is deputy chairman. The session will last a week.

ITALY.

(From our own Correspondent.)

"EVERY inch a king!" Such is the English equivalent for the words of gratitude, admiration, and pride with which Italy, from Turin to Brindisi, from Venice to Palermo, follows the tour of Humbert II. through the cholera-stricken communes. Two years ago, during the disastrous floods in the Venetian territory; last year, after the calamitous earthquake in the island of Ischia; this year, in the choleraic centres of Piedmont—the King has endeared himself to his subjects by his faithful reproduction of that heroic self-abnegation and paternal solicitude on their behalf which they love to associate with his sire, the "*Re galantuomo.*" Modestly attired in a low round hat, with walking-stick in hand, accompanied by the Prime Minister Depretis, by his adjutant, and by the local physicians, he has been visiting every hospital where the cholera patients are housed, going from bed to bed, inquiring into each individual case, taking note of the treatment and its results, addressing genial words of encouragement to the more despondent sufferers, and leaving substantial donations to each institution on his departure. Praiseworthy as such conduct would be in a country like ours, it is trebly so in Italy, where ignorance, superstition, and centuries of insanitary prejudice have added tenfold to the miseries and the dangers of the cholera epidemic. The suspicion of the patients and their friends that the physicians and priests are in league to poison them, or "choke them off anyhow," is but one of the many difficulties of the situation. In Piedmont, the least uncivilised of the Italian provinces, the district medical officers have come upon cabins, wigwams they may be called, where in one room lie huddled together father, mother, and half a dozen children of all ages, some of them moribund; some in the incipient stage of disease; some candidates for other maladies besides cholera, most of them stark naked, and all of them without fresh air, pure water, or wholesome food. Yet, even in these conditions, the medical officers find it next to impossible to remove and isolate the cholera patients. Where these have been torn from their surroundings and placed in some temporary *ricovero*, they have actually crawled back to their hovels, and nothing but military sentryship has sufficed to keep them in their new quarters when again brought back to them. Thanks to the King's visits, this morbid distrust of the medical man and his prescriptions is on the wane, and already in Busca and Cuneo, and their neighbourhoods, the epidemic is in full retreat.

Fortified by the Royal example, public men are redoubling their zeal in enlightening the popular mind as to the causes, the course, and the cure of cholera. A strikingly dramatic scene was witnessed the other morning at Peregallo in Lombardy. It was Sunday, and the people had assembled in crowds to hear the special prayers prescribed by the archbishop to appease the anger of the Almighty and to stay the scourge of cholera. The hour had been changed from the usual one of 10 A.M. to 5 A.M., in order to secure fresher air for the more numerous congregation. The mass was over, and in another minute the kneeling devotees would have risen to disperse, when suddenly a voice was heard sonorously and commandingly bidding them remain, and all eyes turned and fell on an old gentleman in white hair and of ruddy complexion from whom the words proceeded. In dead silence he spoke to the following effect:—"I take the opportunity of finding you assembled here to say a few words to you on the cholera. Your good priest, Don Antonio, by order of the excellent archbishop, has engaged you, as becomes his office, in matters which concern the soul. I as a layman and a member of the Communal Committee of Public Hygiene, will speak to you on matters which concern your body. Life has been given us by God, and it is our duty to guard it well and preserve it as long as possible; and I believe I am not desecrating this place by telling you how this, in the present circumstances, is to be done. The cholera is in full career throughout Italy. Workmen—mechanics without conscience, flying from the cholera-smitten towns of France, where they were employed, violating the sanitary cordon placed by Government on our confines, and refusing to submit to quarantine, where, after all, they are lodged and boarded gratis—have penetrated into the heart of Italy and carried the disease into many districts. So long as the danger was remote the syndics took precautions, and nothing more was thought of it. But now it is at our gates. Milan, Monza, and this neighbourhood have hitherto escaped attack; but not so Bergamo, Lodi, Treviglio, and Pescarenico. With the easy and frequent communication now established, we may from one moment to another have the enemy upon us, and we must therefore be prepared to repel it. First of all, let me enjoin on you cleanliness—cleanliness of your bodies and of your dwellings. Next, moderation in drinking and in eating. Finally, and above all, if any of you should have the ill-fortune to be seized with the malady, give immediate notice of the fact; prompt remedies can save you when delay would be fatal. We see how, by culpably persisting in concealing the outbreak at Spezia, the cases rose in twenty-four hours to sixty, of whom thirty-nine died. Yesterday I heard someone in his ignorance say, 'If I were seized with cholera, I would conceal the fact so as not to be taken to the lazaretto,' which is, when all is said and done, a pleasant enough domicile, quite isolated, with an agreeable exposure, conceded *ad hoc* by our excellent member of Parliament, Count Rinaldo Taverna, 'because,' added the individual, 'they give the patients poison there, of which they are sure to die.' These impressions are follies, which ought neither to be conceived nor uttered. Is it not the fact that the moment you feel ill, say with headache, you at once send for the doctor, and if he does not arrive forthwith and prescribe for you, you angrily upbraid him? And why is it that in the case of cholera you keep the physician at arm's length for fear he would hasten your death with poison? Does he not come to you in such a malady to the great risk of his own life? Would it not be less dangerous for him to leave you alone to die than come all the way to poison you? What interest can the medical man and the communal authorities who appoint him have in causing your death, when they would thereby be putting your widow and your orphans on the charity of the commune, which would have the burden of maintaining them? Be advised, then. The poison you seem to dread, given opportunely and in the proper dose, will be your salvation. You have seen my father, who, thanks to laurocerasus, which is a powerful poison, was cured, and lived for fifteen years, and yet a teaspoonful of it would kill you. It is a duty of conscience I am imposing on you. All of us have our lives at stake. I, in spite of my seventy-two winters, who would have but little to lose if I were stricken down with cholera, will continue to wear my flannel shirt and send for the first medical man the moment I require him."

The effect of this brief address was electrical. The people left the church profoundly impressed, and the harebrained chatter about avoiding the lazaretto, with its doctors and their drugs, has been heard no more in Peregallo. And who was the speaker? He turned out to be Signor Carlo Curti, a landed proprietor in the neighbourhood, a communal councillor, a patron of the Church, and superintendent of the communal schools. The leading Milanese journal printed the address pretty much as I have given it, and it is now being copied and circulated in other provinces, where it is much more required than in Lombardy.

In deplorable contrast to the wise words and philanthropic attitude of Signor Curti is the conduct of Signor Oliva, a well-known member of the Italian Parliament. On arriving at the Roman railway terminus, he declined to submit to the fumigation imposed on all passengers, and even used violence to the delegate of public security who was about to turn the carbolic spray upon him. Granting that such fumigations are medically useless, he had no right to contravene the orders of the Government. It would have cost him little to have undergone the process, which, be it remarked, reassures a vast number of his fellow citizens, and saves them from the panic which often invites the disease it dreads. The *Opinione* comments severely on the churlish demeanour of the *borné* lawgiver, and anticipates, on the reassembling of Parliament, a searching interpellation on the subject.

Rome, Sept. 1st.

HOSPITAL SUNDAY AT WESTON-SUPER-MARE.—The appeal on the 31st ult. in the churches of Weston-super-mare in aid of the local hospital produced £265. The offertories from other denominations are not yet complete, but is is hoped that these, with the out-town collections, will swell the total amount of the Hospital Sunday effort to £450.

Obituary.

FREDERICK CHAMBERS, L.S.A., J.P.

THIS old and highly esteemed practitioner died on Aug. 21st, aged eighty-three, at his residence, Vicarage-crescent, Margate. His death was caused by old age and the depressing effect of an abscess in the foot, the result of a suppurating corn; grief for the loss of his wife, who had died a few months before, having previously brought him into a low condition of health. Mr. Chambers studied at the London Hospital in the days of Sir William Blizard and Dr. Ramsbotham, and the history of his early life carries us back to the memory of the past. In 1820, whilst a ship-surgeon, he visited Pitcairn Island and stayed a fortnight with John Adams, of the *Bounty*; after travelling in various parts of the world he resumed his studies at the London Hospital, and in 1832 passed the Apothecaries' Hall. Subsequently Mr. Chambers carried on a successful practice in the Hackney-road for thirty-six years, after which he retired and settled in Margate, where he remained till he died. His residence in Margate proved a real blessing to the town. He found the place in a wretched sanitary condition; the inhabitants drank water from polluted wells, and pigstys and filth were everywhere paramount. In spite of abuse and opposition, Mr. Chambers fought earnestly and untiringly in the cause of sanitation; he attacked abuses without fear or favour, and in time brought about a better state of things. For many years he was a leading spirit in the town; he was three times mayor, was a guardian of the poor, a justice of the peace, and filled various other honourable and unpaid offices.

Mr. Chambers was esteemed and respected by all, but probably only his more intimate friends knew the full worth of his character; his love of truth, his hatred of all sham, and his staunch and never-failing friendship rendered him especially dear to these. His funeral, which took place at Margate on Tuesday, the 26th ult., was attended by the Mayor and corporation, and by his relatives and friends.

JOHN POPHAM, M.A., M.B.

WE regret to have to record the death in his seventy-eighth year of an old member of the profession and public servant, Mr. John Popham, late of Cork. He was a scholar, senior classical moderator, and Berkeley gold medalist of the University of Dublin. He held the M.B. of Dublin and of Cambridge, the licences of the King and Queen's College of Physicians, Ireland, and the membership of the Royal College of Surgeons of England. Mr. Popham was for many years senior medical officer to the Cork Union Workhouse and for nearly forty-two years physician and chemical lecturer to the North Infirmary, Cork, once local secretary to the medical section of the British Association, and lecturer on materia medica to the Cork School of Physic. His contributions to the periodical medical press were both numerous and valuable. About two years ago he retired from practice and went to reside at Ealing, where he died on the 26th ult., after a few days' illness, of bronchitis and syncope of the heart, accelerated by the effects of an accidental fall.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 28th:—

Davies, Howard, The Ash Grove, Pontypridd.
German, Hanway, Maywood, Sevenoaks.
Green, C. R. Mortimer, St. Simon's Vicarage, Morpeth-street.
Uddin, Tamis, Pump-court, Temple.
Wharry, Henry Gordon Oliphant, Gordon-square.
Wood, Edward, Oakley, Lansdown-road, Tottenham.

The following gentleman also on the same day passed the Primary Professional Examination:—

Congdon, George Julius, Guy's Hospital.

BRITISH MEDICAL SERVICE.—In the list of successful candidates published last week, for "H. P. James" read "H. D. James."

ON their visit to Hull next month, the Duke and Duchess of Edinburgh have consented to take part in the ceremony of laying the foundation stones of two wings to be added to the Hull Infirmary.

ACCIDENT TO A GYMNAST.—Another case of serious injury resulting from perilous gymnastic performances has occurred at Blackpool. It is surely time these sensational exhibitions were prohibited, in the interest alike of audience and performers.

TWO remarkable cases of blood-poisoning in Suffolk have been reported. In one of them the morbid process seems to have been induced by a slight wound of the arm resulting from a fall on stubble; in the other case a farm labourer cut his finger with a wheat straw, the arm became greatly swollen, and the man died.

IN the endeavour to ascertain the cause of a serious outbreak of fever which occurred in Beverley a short time ago, the municipal authorities commissioned an eminent sanitary engineer to investigate the health conditions of the town. The report presented by that gentleman inculpates the water-supply—a charge which the water company repudiates, and undertakes to refute.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The following is the list of officers for the ensuing session: President: Mr. F. Lawrance. Vice-Presidents: Drs. Alderson, Travers, Thudichum, and Pickett. Council: Mr. Barnes, Dr. Clippingdale, Mr. Swinford Edwards, Mr. Hemming, Mr. J. R. Lunn, Mr. Potter, Mr. Walker, Dr. Hart Vinen, Mr. R. F. Benham, Mr. C. B Keetley, Dr. Owles, and Surgeon-Major Scriven. Treasurer: Mr. Alfred Cooper. Secretaries: Dr. Campbell Pope and Mr. Gunton Alderton. Meetings are held on the first Friday in each month, at 8 P.M., at the West London Hospital.

HAWICK COTTAGE HOSPITAL.—The memorial stone of this hospital was laid with masonic honours on the 30th ult. by the Earl of Mar and Kellie. The scheme for the erection of the hospital originated in 1882, when the surplus of the proceeds of the Combe Lectures by Dr. Andrew Wilson formed the nucleus of a fund which now amounts to nearly £3000. The building, which will contain fourteen beds, with space for more, will, with the grounds, cost about £1600, and the remainder of the funds will be applied towards the maintenance of the institution.

THE MALODOROUS LIFFEY.—The recent sultry weather has made this river a source of annoyance to the citizens of Dublin by the disgusting effluvia emanating from it at low tide. That these noxious gases must be deleterious there can be no question, and from a sanitary point of view the river is a disgrace to the corporation and citizens. The subject is ventilated and brought into notoriety every summer, and then gradually subsides until again resuscitated the following year. The main drainage scheme in the present highly taxed condition of the city seems impossible; but some more economical method which would remove the nuisance might surely be adopted.

SUICIDE OF A SURGEON.—The "Australasian Medical Gazette" reports the following sad event:—Mr. Griffith Job Jones, L.R.C.P. Edin., 1879, M.R.C.S. Eng., 1880, a medical officer connected with the Destitute Asylum, committed suicide in the York Hotel, Adelaide, on June 22nd, by taking a large quantity of chloroform. In a letter addressed to Dr. Way he gives as a reason for the rash act the inquiry which was pending as to the outbreak of ophthalmia amongst the Industrial School children at Magill that were under his charge, which appointment he had held for about six weeks. The deceased was twenty-six years of age.

DUBLIN MEDICAL STUDENTS' CLUB.—Several members of the medical profession resident in Dublin have issued a circular appealing for aid in starting a "furnishing fund" for this Club, which has hitherto, it is satisfactory to note, been self-supporting. The sum of £200 is asked for, and it is requested that contributions may be sent to Mr. W. G. Tetman, L.R.C.S.I., 91, Harcourt-street, Dublin. The circular is signed by Messrs. J. Kai Barton, President of the Club, Session 1882-83; W. L. Wheeler, President of the Club, Session 1883-84; D. J. Cunningham, Vice-President; W. Stoker, Vice-President; F. J. B. Quinlan, Vice-President; Wo Thursley Stoker; T. Alnutt Nixon; and W. G. Toomey, LL.D., who undertake to supervise the disbursement of all sums contributed, and to see that they are applied only to the purpose for which the money is subscribed.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BATTEN, GEORGE B., M.B., C.M.Ed., has been appointed Assistant Medical Officer to the Fife and Kinross District Asylum, Cupar.

BERESFORD, CHARLES WILLIAM, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Markyate-street District of the Luton Union, vice Mackey.

BURRY, HENRY B. PULLEN, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Petersfield Union, vice Pearse.

CORNER, M. CURSHAM, L.S.A.Lond., has been appointed Resident Medical Officer to the Tower Hamlets Dispensary, vice Samuel E. Pritchard, L.R.C.P.Lond., M.R.C.S., deceased.

FORSYTH, WILLIAM, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Tirhut State Railway, and stationed at Mozafferpur.

FOWKE, FREDERICK WILLIAM, M.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Priors Marston District of the Southam Union, vice Culhane, resigned.

LOWE, GEORGE, M.B., C.M. St. And., L.R.C.P.Ed., has been appointed Medical Officer for the Eighth District of the Depwade Union.

MASKEW, JOHN S., L.R.C.P.Ed. &c., has been appointed a Medical Officer to the New Forest Union, vice R. W. Jenkins, deceased.

SPICER, R. H. S., M.D., has been appointed Medical Officer and Public Vaccinator for the North Molton District of the South Molton Union, Devon, vice James Flexman, resigned.

VIANT, HY., L.R.C.P.Ed. &c., has been appointed Medical Officer of Health for the New Forest Rural District, vice Jenkins, deceased.

WHITE, BARRINGTON STER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Horsmonden District of the Tonbridge Union.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On the 30th ult., at Clifton-gardens, W., the wife of G. D'Arc Adams, M.D., of a daughter.

GAYFORD.—On the 28th ult., at Lady Margaret-road, London, N., the wife of Charles Gayford, M.R.C.S., late of Hoshangabad, C.P. India, of a son, stillborn.

GRAY.—On the 29th July, at Cinnamara, Assam, the wife of Edward Gray, M.B., C.M., of a son.

LANKESTER.—On the 29th ult., at Gwendwr-road, West Kensington, the wife of Herbert H. Lankester, M.R.C.S., of a daughter.

MARRIAGES.

BUCK—BEARE.—On the 30th ult., at the Church of St. Leonard, Streatham, London, Charles William Buck, M.R.C.S., of Settle, son of the late Richard Hardacre Buck, of Settle, Yorkshire, Solicitor, to Emma Foote, third daughter of William Beare, of Roboro Villa, Streatham, S.W., and Rathbone-place.

LATHAM—BERNARD.—On the 28th ult., at the Parish Church, Whitby, Peter Wallwork Latham, M.B., Downing Professor of Medicine, Cambridge, to Annie Frances Bernard, second daughter of the late James F. Bernard, of Clifton.

PARSONS—COLE.—On the 23rd ult., at St. John's, South Hackney, Charles W. Parsons, M.R.C.S., L.S.A.Lond., to Alice, eldest daughter of H. B. Cole, Esq., of Hackney.

SEWELL—WHITELAW.—On the 26th ult., at Rowmore, Row, Dumbartonshire, by the Rev. William Dunn, of Cardross, William R. Sewell, M.D., of Helensburgh, to Jessie, daughter of Alexander Whitelaw, Esq.

STRADLING—RENNY.—On the 29th ult., at St. James's, Shirley, Hants, William Arthur Stradling, M.R.C.S., C.M.Z.S.Lond., &c., of Watford, to Emmaline Isabelle (Lina), second daughter of Thomas Renny, Esq., of Durham Lodge, Shirley, and Arequipa, Peru.

DEATHS.

BROWNE.—On the 30th ult., at Ramsgate, after a brief but painful illness, John Collis Browne, M.D., late H.M. 98th Regiment, aged 64.

GARRARD.—On the 27th ult., suddenly, at his residence in Kington, Herefordshire, George Samuel Garrard, M.R.C.S., in his 59th year.

LYDALL.—On the 28th ult., at Exmouth, Devon, Wykeham Hawthorne Lydall, L.R.C.P.Ed., late of Mecklenburgh-square, London, aged 46.

MICHAEL.—On the 29th ult., at 1, The Circus, Bath, Surgeon-Major David Michael, F.R.C.S.E., in his 52nd year.

WORSLEY.—On the 30th ult., at his residence, Hornby House, Heywood, near Manchester, James Henry Worsley, M.R.C.S.Eng., aged 43.

YOUNG.—On the 31st July, at Bequia, St. Vincent, West Indies, James Justine Henry, infant son of James Vance and Mary Louisa Young, aged 14 days.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday next, Sept. 13th. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

AN "UNPROFESSIONAL" DOCTOR.

THE author of "Between the Heather and the Northern Sea"—a capital tale appearing in *Good Words*—thus describes one of the characters in the story: "Dr. Armitage was a man whom it was good to have near you in such a moment [a case of sudden and serious illness]. He was the most unprofessional of professional men. Though you had stood by a dozen sick beds with him, you did not associate him with the sickness or with the gloom, but rather with all alleviating things—the smiles, the small pleasantries, the newest bit of lively news, the first hope he had given you, the last laugh he had had over your too tearful despondency. If he had been with you in a dark moment, you only remembered his skill, his quiet strength, his unfailing sympathy."

St. George's.—Notably in therapeutics.

TREATMENT OF THE BITES OF THE 'HARVEST BUG."

To the Editor of THE LANCET.

SIR,—Dr. Cornelius Fox's letter of inquiry as to relief from the bite of the "harvest bug" (Septus autumnalis), and Dr. C. S. Taylor's reply, containing careful preventive measures by sulphur fumigation, are interesting; for only those who are worried by these autumn pests can sympathise with any effort to rid themselves of them. I have been staying at the picturesque and healthy little seaside resort of Hythe, near Folkestone; and being troubled with these pests, I found a liniment composed of a drachm of spirits of chloroform and camphor, and two grains of bichloride of mercury, to four ounces of rosewater, a good application to allay the irritation caused by them. The character of the insect, together with the symptoms caused by the bite, are described in my Lectures on Parasitic Eruptions of the Skin, published by Messrs. Lewis and Son in 1881. A little camphorated oil rubbed into the skin of the legs and arms will generally prevent these attacks.

I am, Sir, yours obediently,

Sackville-street, W., Sept 2nd, 1884. JAMES STARTIN.

THE LATE DR. MILLER OF SOUTHSEA.

DR. H. A. MARTIN of East Cosham, Hants, presents his compliments to the Editor of THE LANCET, and will feel greatly obliged by his permitting a copy of the enclosed to be inserted in the next issue of his journal, on behalf of the widow of the late Dr. Moore Miller, J.P., Southsea, who died in July last, leaving her in very straitened circumstances.

"Some friends of the late Dr. Miller are desirous of presenting his widow with some substantial mark of their appreciation of his merits, and of their respect for his memory. Any donation will be gladly received by Captain McCoy, Elm Grove Villa, Southsea; or can be paid into Messrs. Grant and Co.'s Bank, Portsmouth or Southsea, to the joint names of Admiral Chads and Captain McCoy."

Atropos.—Dr. Burney Yeo on Health Resorts and their Uses (Chapman and Hall).

Mr. R. Durdin will find in our next number the information he desires.

"SKILLED NURSING."

To the Editor of THE LANCET.

SIR,—As the letter in your issue of last week signed "E. Faithfull" is in many respects misleading, and evidently written without a clear knowledge of facts, may I, as the superintendent of an institution for nurses, say a few words in reply? First, a nurse does not (except in monthly nursing, in which the training is short, and consequently has to be paid for, as the nurse quits the hospital as soon as she is efficient) expend a considerable amount of money in attaining proficiency. Time, as a matter of course, she must give, but no longer than would be required to turn her out a thorough dressmaker or lady's maid. In all general hospitals a nurse receives a salary almost from the first, and uniform after the first few weeks. If at the end of her training she elects to enter an institution, she receives a salary of from £20 to £25 per annum, according to her capabilities, and in some homes uniform as well, and "everything found." She has only her clothes to provide from her salary, and if she has only herself to keep she ought to be able to save at least from £7 to £10 a year. Added to her salary must be taken into consideration the presents in money or other things that she often receives. Miss Faithfull says a nurse in an institution earns but a "bare subsistence," and that all her earnings are forfeited to the home, as if the nurse received no equivalent. But if we look at facts it is not so. Say a nurse gets, as mine do after their first six months' service, £25 per annum, and when not at work 1*s.* 6*d.* per week laundry money; reckon her board at 10*s.* a week and her lodging at 5*s.*, and she is receiving the equivalent of nearly £70 per annum, without including extras or beer money. In few employments would she make more money with less trouble. Now as to the non-resident nurses. Some institutions do, I believe, take half the fee; none more than half, and some only 5*s.* in the guinea. The rate of fee is certainly fixed by the institution; but the nurse knows what it is before she undertakes it, and the fact that many nurses prefer to work in this way proves that it cannot pay them badly. Miss Faithfull further speaks of nurses being harassed with many restrictions, and mentions two. That regarding the testimonials is not correct in all cases. I myself only hold the testimonials that the nurse earns in my service, and which is, in fact, a private communication to the institution. These are always at hand, if needed, and it is a common thing for a nurse to ask a patient for a duplicate for herself. In the interests of our clients we could not permit nurses to be transferred from one patient to another without our knowledge, as this would leave them at liberty to throw up any case, however critical, for one more lucrative.

There are, as your advertisement columns testify, many good existing institutions in London, to say nothing of suburban and country ones; and I think it would be far better to encourage the already existing institutions, all of which have been patiently worked up and perfected by experience, and so enable them to offer higher pay to their nurses, than to start fresh ones. I will venture to state as a fact that the lot of a nurse in one of the homes Miss Faithfull writes to disparage is far superior as to comfort and independence to that of many governesses; and I hope other institutions will speak up for themselves, and prove that our nurses are earning more than a "bare subsistence," and that if they do not save it is generally their own fault.—Yours faithfully,

ELINOR AGNES BEDINGFELD,
The Belgravia Institute for Trained Nurses, Superintendent.
Vauxhall-bridge-road, Sept. 2nd, 1884.

*** Several other letters on the above subject have reached us, but our space will not allow of their publication.—ED. L.

CURIOUS FACT IN NATURAL HISTORY.

To the Editor of THE LANCET.

SIR,—I wish to communicate a curious and, so far as I know, unprecedented fact in natural history.

A tenant of mine near London had a pet dog and cat. Lately the cat was delivered of a litter of what should have been kittens, but which appeared to be a cross between the dog and cat. The gardener's wife, who assisted on the occasion, states that there was a litter of four, born dead. All of them had puppies' heads and forelegs, and the hinder parts like kittens. The mother was so much injured that she had to be killed. They were all buried before I heard of it.

I am, Sir, yours truly,
Wing Vicarage, Leighton Buzzard, Aug. 25th, 1884. P. T. OUVRY.

CHOLERA AND SUPERSTITION.

EVEN the most civilised countries are remote enough from that sanitary millennium when every citizen shall have been taught to be "the intelligent custodian of his own health"; but surely the revelations of the *Echo di Bergamo* point a very serious moral to the Government of Italy. "The prevailing superstition," says that journal, "is incredible, and not confined to the people only. Everyone shares it. Physicians are distrusted. Medicines are suspected. We know of a place where people are ready to swear that the district doctor receives twenty lire (sixteen shillings) for every cholera patient who dies under his treatment, and that when his victims amount to a thousand he is rewarded with a pension! The result of this deplorable superstition, of which we could give many more examples, is that not only is the physician never sent for in time, but when he arrives his services are refused. Moreover, as it is generally the priests who send for him, the suspicious friends of the patient, knowing this, decline to call in the priest. Both priest and physician generally reach the bedside when the patient, quite capable of being rescued a few hours earlier, is past prescribing or praying for." Thus far one of the leading journals of Northern Italy. Another journal tells us that of the (about) 30,000,000 Italians more than 16,000,000 are *analfabeti*—i.e., can neither read nor write.

Dr. T. W. Hime.—The notice appeared in our last issue, page 370.

F. B.—We do not give medical advice.

CURIOUS CAUSE OF DISLOCATION OF THE SHOULDER.

To the Editor of THE LANCET.

SIR,—The following case of the true "subclavicular" form of dislocation of the shoulder may be of interest to your readers, not so much from the comparative rareness of the injury as from its unusual cause.

F. T——, aged nineteen, a muscular young man, was swinging himself standing on the seat of a garden swing. Whilst alternately lowering and raising his body by bending his knees, to propel himself, and with his hands extended over his head grasping the ropes, he suddenly "felt something give in his left shoulder-joint," the shock causing him to fall to the ground, though without striking the injured limb. On my stripping the patient's chest a well-marked case of complete "subclavicular" dislocation of the shoulder presented itself. The head of the humerus was seen to be lying quite internal to the coracoid process, and occupying the space just under the middle third of the clavicle, the coracoid process itself projecting considerably, with a very marked depression beneath it. An attempt to reduce the dislocation was made without anæsthesia being induced; but, on account of the pain caused by movement and the nervousness of the patient, it was not persevered in. However, under the influence of ether the head of the bone was easily brought into its proper cavity by appropriate traction, with the heel in the axilla.

The case is worthy of record as showing the great amount of muscular action that must have been exerted to have produced so marked an injury.—I am, Sir, yours truly,

HERBERT E. FRIEND, L.R.C.P. Lond.

Talbot-road, W., Aug. 23rd, 1884.

ALCOHOLIC PARAPLEGIA.

To the Editor of THE LANCET.

SIR,—In your issue of June 28th mention is made of alcoholic paraplegia. As far back as fifteen years ago two cases of alcoholic paraplegia came under my treatment at Lucknow. The abuse of alcohol was not given up, and both died. Some years after a third case came under my notice. I do not know whether he died, as I lost sight of him. There is a person buried in the cemetery here, who, I am told, died of paraplegia; he also had been a hard drinker. All these cases occurred in men. The spinal nerve centre of the lower extremities appears to have been the region most affected. Some years ago a case came under my notice in a person who was certainly not addicted to an excessive use of alcohol. On sitting down to dinner and drinking a glass of sherry he would experience a curious feeling of helplessness in his lower extremities, which passed off by taking food and more wine. It appears that the first impact of his alcoholised blood on the nerve-centre of his lower extremity produced these phenomena. Such a person, had he habitually drunk to excess, would very probably have had paraplegia. Why this nerve-centre should be specially affected I do not know; but there appears to be some elective action on the part of this centre for alcohol. The want of coördination in the movements of a drunken man's legs must, I think, depend on this same effect of alcohol.

I am, Sir, yours truly,
E. BONAVIA, M.D.,
Etawah, India, Aug. 8th, 1884. Surgeon-Major, I.M.D.

PERFORATED RUBBER KNEE-CAPS.

To the Editor of THE LANCET.

SIR,—Under the heading of "New Inventions" in your last issue Mr. Thomas of Birmingham introduces an indiarubber knee-cap with perforations. Stockings and knee-caps on this plan were introduced more than thirty years since. They were tried by practical men, and may say never came into use, as their great inferiority to other contrivances was manifest.

I am, Sir, yours truly,
Old Cavendish-street, W., Aug. 29th, 1884. EDWARD HUXLEY.

F. J. B.—1. 300 cubic feet, if there exist proper means of ventilation by windows and chimney.—2. According to the quality of the gas. A cubic foot of gas in combustion will unite with from 0·9 to 1·64 cubic feet of oxygen, and produces on an average 2 cubic feet of carbon dioxide, and from 0·2 to 0·5 grains of sulphur dioxide. In other words, a cubic foot of gas will destroy the entire oxygen of about 8 cubic feet of air. One cubic foot of gas will raise the temperature of 31,290 cubic feet of air 1° F. Wolpert has calculated that for every cubic foot of gas 1800 cubic feet of air must be introduced to dilute properly the products of combustion. A common small gas-burner will burn nearly 3 feet per hour, and will consume 10, or probably 12, cubic feet in an evening of four hours, and therefore from 18,000 to 21,600 cubic feet of air must be introduced for this purpose alone in the four hours, unless the products of combustion are removed by some special channel.

WHAT IS A MINIM?

To the Editor of THE LANCET.

SIR,—Having sought an answer to the above question in various dictionaries, with no more satisfactory result than to learn that it is "the smallest liquid measure—a single drop," I next referred to Thompson's "Conspectus of the Pharmacopœia," hoping to find there at least some safe indication. In the appendix to that invaluable little compendium I find the minim defined, by its relation to the fluid drachm and ounce, as $\frac{1}{480}$th part of "a gallon"; but it is only by the juxtaposition of an identical subdivision of the "wine gallon" that I infer that it is to the wine gallon that the minim is thus related. Now, the wine gallon is known to contain 231 cubic inches, while the imperial gallon contains 277·274. Hence the two stand to each other in the practically exact proportion of 5:6. Therefore, since the weight of the "imperial gallon" (of water) is, by law 10 lb., or 70,000 grains, that of the "wine gallon" will be five-sixths of 70,000 grains; and consequently the minim (of water) must weigh $\frac{5}{6} \times \frac{70000}{480} = \frac{350000}{2880} = 0{\cdot}9494$ gr.—which is for all practical purposes the same as $\frac{1}{19}$ths of a grain; in other words, twenty minims of water weigh nineteen grains, and one fluid drachm weighs fifty-seven grains.[1]

Now, before I had worked out this theoretic result, I had sought for one practically by weighing a minim glass filled up to the sixty-minim mark (having first counterpoised the empty glass), and had found the weight to be 54·6 grains. It might, of course, be a mere accidental coincidence; but it is to be noted that at this rate eight drachms, or one fluid ounce, weighs 437 grains, which (allowing for an error of one-tenth of a grain in my measurement, thus bringing it up to 437·6) is exactly one ounce avoirdupois.

Now, whereas the proper weight of one fluid drachm is 57 grs., and the actual weight by trial of the contents of a drachm measure was found to be 54½ grs., or one-eighth of an ounce avoirdupois, the question arises whether the manufacturer confused the fluid and the avoirdupois ounces, or only made a grossly erroneous measure which accidentally tallied with the wrong one. The former seems much the most likely solution, which would be easily tested by the examination of several glasses; and it is to draw attention to what I conceive to be a systematic blunder that I make this communication.—Yours obediently,

J. HERSCHEL, Lieut.-Col. R.E.

Collingwood, Hawkhurst, Sept. 2nd, 1884.

INFANTILE CIRCUMCISION.

To the Editor of THE LANCET.

SIR,—Having been asked to circumcise a new-born infant, and being away from any suitable book of reference, will any of your correspondents kindly tell me the simplest method of doing so, especially as to number and kind of sutures used in the operation, local anæsthesia, &c.?

I am, Sir, yours obediently,

Aug. 27th, 1884. FOREIGN PRACTITIONER.

*** Local anæsthesia is not to be recommended. Draw the prepuce in front of the glans, and grasp it there between the parallel handles of a pair of scissors or some similar body, and shave it off by cutting close in front of the scissors; then allow the skin to retract, slit up the mucous membrane along the dorsum, and turn off the two flaps so made, taking care to go quite back over the corona glandis. These mucous flaps should be pared off a little, and then stitched to the skin by a continuous suture of fine catgut; this secures exact apposition, and does not require removal. A long narrow strip of boracic acid lint should then be firmly wound around the part, leaving the end of the glans exposed for micturition; and every time the parts are wetted with urine they should be thoroughly soaked with a saturated solution of boracic acid in water, and the dressing may be left on for a week or ten days, when the wound will be found healed. Care should be taken to remove first the skin which covers the glans. In infants the slight hæmorrhage is generally best controlled by placing the penis in a sponge, and grasping it firmly for a few moments.—ED. L.

[1] Should any reader be able to find this relation of the minim to the grain elsewhere stated, it would, I think, be satisfactory to others as well as myself to obtain a reference to the authority. Meanwhile, it is at the same time corroborated by the common belief that the minim and the grain are almost convertible terms, and also helps to explain that belief. That this belief, however, should be so deeply rooted as to find expression in actual graduation of glasses, I should certainly not have expected.

Mr. J. C. Richardson.—There is no definite arrangement on this subject. Some coroners are very chary of supplying copies of depositions to the public; others will do so freely, on payment of a clerk's fees for paper, copying, &c.; as so much a folio. Generally, if the person desiring information can supply the correct name of the deceased and the date of the inquest, the coroner's clerk will, on personal application, answer any questions gratis to a *bonâ fide* inquirer.

Dr. Ward (Sutton Coldfield).—In an early number.

POISONING BY ICE CREAM.

To the Editor of THE LANCET.

SIR,—In your issue of Aug. 2nd a few lines are devoted to the statement that a large number of people have been recently poisoned in Brooklyn by acetate of copper contained in ice cream. As a practitioner who had ten of these cases to treat during the night of July 4th, perhaps you will allow me to state the facts in these interesting cases.

Mr. G. H. G——, a confectioner of Brooklyn, N.Y., doing business at No. 829, Fulton-street, prepared a large quantity of ice cream of various flavours for sale during the day and evening of July 4th, most of which was sold in the usual course of trade, part being eaten at the shop, and part being delivered in freezers at private residences, the manufacturer and his family also freely partaking of the delicacy. From midnight of July 4th the physicians of that part of the city known as "The Hill" were busily engaged in relieving the sufferings of about 130 people who had eaten cream prepared by Mr. G——. The symptoms in all the cases were severe pains in the hypogastric and epigastric regions, with violent vomiting and purging, and in many cases serious collapse, with blueness, coldness, and shrinking of the skin, very like that seen in cholera. About a dozen cases were more than a week in perfecting convalescence. So far as I know, none of the victims observed any unpleasant taste with the cream; at all events, the confectioner and three of his family were among the sufferers. Some stupid persons started the acetate of copper cry, and it was of course published in the daily papers before, unfortunately, being corrected to *lactate* of copper, as it was said the cream must have been sour; but no metallic taste was noticed, nor were the tinned copper freezers found to be at all worn, so as to permit erosion of the copper.

An analysis was ordered at once by the Board of Health, and the result, communicated to the Board on July 14th, 1884, by Dr. H. H. Bartley, chemist to that body, was substantially as follows. The flavours used were vanilla and lemon, both properly made from the natural fruits. No metallic or other poison was found. The results depended somewhat on idiosyncrasy, as not all who partook became ill. In one case six persons ate freely of the cream, only four being made ill thereby. During the analysis of the cream Dr. Bartley noticed an extremely fetid odour evolved. This would seem to suggest that the cream, even before freezing, could not have been in sound condition; but as the cream came from two out of twenty-seven packages sent from the country, the other twenty-five causing no illness when made up into ice cream, and as the ill-fated two cans of Orange County cream represented the joint product of fifty-two dairies, it has hitherto been found impossible to point out the dairy whence the bad cream came. The illness was certainly not due to metallic poisoning; it may have been caused by the development of some of the very numerous alkaloids of decomposition, of which the "ptomaines" are best known—the so-called "cadaveric alkaloids."

So far as known no fatal cases have presented themselves; many of the patients have, nevertheless, been dangerously ill.

Within a few weeks another, but much smaller, series of cases has occurred in this city, due apparently to the use of artificial vanilline ($C_7H_5CH_3O_3$) or methyl-proto-catechine aldehyde—very far from being a stable body. The symptoms were somewhat similar, but the distress greater, and the prostration very marked.—Yours truly,

NELSON B. DE S. SIZER, M.D., B.Sc. (Neo-Ebor. Univ.).

Brooklyn, N.Y., Aug. 19th, 1884.

THE LATE DR. HILTON FAGGE.

To the Editor of THE LANCET.

SIR,—Dr. Moxon's sketch of the late Dr. Hilton Fagge is so true to life, so remarkable for its beauty of thought and intellectual vigour, and for its reflected interest as between the public and the profession, that I venture to express the hope that Dr. Moxon may be induced to reissue it in the pamphlet form.—I am, Sir, yours faithfully,

Sept. 3rd, 1884. X.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 13, 1884.

ADDRESS TO STUDENTS.

As we show elsewhere, the hope for legislation in the interest of medical education is not merely deferred, it is killed; and the student who is now about to join our schools is little likely to see any change during his pupilage. We shall therefore make a few practical remarks, which may be useful in guiding him through the mazes of the different systems laid down by the twenty examining boards at present in existence.

Every medical student must pass a Preliminary Examination in Arts before he can register the commencement of his professional studies. This Preliminary Examination varies in severity from the Special Examinations held by the College of Preceptors and by some of the medical corporations, such as the Society of Apothecaries, to the Matriculation and Previous Examinations of the Universities; that of the University of London being pre-eminent for severity and extent of range. In all cases, English language, English history, geography, Latin, elementary mathematics and elementary mechanics are compulsory, and an option is allowed between Greek, a modern language, logic, and the rudiments of one of the natural sciences, as botany or chemistry. In many modern schools these subjects are selected for the Local Examinations held by the Universities of Cambridge and Oxford, and by this means a boy may pass a sufficient preliminary during his ordinary school course. Such an examination could easily be passed, one would suppose, by any average schoolboy; but the rejections at the least exacting of the examining boards are still very numerous, and average considerably more than 25 per cent. That the standard is not unnecessarily high is the testimony of every medical teacher, and becomes obvious at every subsequent technical examination at which the student has to appear. Practice in English composition and accuracy in spelling would seem to be passed over by many schoolmasters as of little consequence, while other subjects of less importance are cultivated to excess. Whatever opinion may be held respecting the relative merits of Classics *versus* Science, in the preliminary or general education, it must not be forgotten that the methods of Medicine are for the most part identical with those of so-called Natural Science, and hence an accurate training in mathematics and the education of the observing faculties in some branch of natural science are essential to the future medical student and practitioner. Perhaps the ideal education for a medical student would be, first of all, a good literary and classical education, and then at least a year's training in those branches of natural science that are most intimately connected with medicine—namely, Physics, Chemistry, and Biology. If, however, a boy, intended for the medical profession, gives promise of good literary attainments and has a gift for the rapid acquisition of languages, we should strongly recommend his being taught Greek instead of the now fashionable German. Latin is of course a necessity to every student of medicine. We need not here enter into any controversy as to the superiority of Greek over German literature, but would merely point out that unless a knowledge of the former language is obtained at school, it will rarely be acquired afterwards; whilst German, like French, is best learnt where it is spoken; and a year or two's study in foreign schools of medicine is a most valuable means of enlarging one's views on the nature, and improving oneself in many details in the treatment of medical and surgical affections. Medicine is cosmopolitan, and ignorance of the methods and theories of our continental neighbours will soon be considered a disgrace to us, rather than the badge of a boasted superiority.

Medical studies may be commenced either by attendance on lectures at a recognised medical school, by attending the practice of a recognised hospital, or by becoming the pupil of a legally qualified medical practitioner holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or having some similar opportunities of affording practical instruction. In all cases a certificate must be forwarded to the General Medical Council within fifteen days from such commencement. Most students now go direct from school to the medical lecture-room and hospital, and by doing so no break takes place in their education, and their habits of discipline are maintained. Technical instruction is at once engrafted on their general culture, and the student merely passes from one course of study to another; and great advantages may be urged for this plan. The BOB SAWYERS, BENJAMIN ALLENS, and RODERICK RANDOMS of fiction were largely the outcome of the indolent and vicious habits which the old apprenticeship system so rigorously insisted on in former days did so much to foster. Five years of more or less idleness in the country were ill calculated to provoke hard work and industry when the apprentice was transformed into the student "walking the hospitals" without supervision or guidance. A year in a provincial hospital, or with a general practitioner who can devote some time to instructing his pupil in some of the scientific branches as well as in the practical routine work of the profession, would be well spent. In most towns teachers of the various sciences can now be obtained, and in this way a year can be profitably spent in the country in the study of the preliminary sciences of physics, botany, inorganic chemistry, and general biology before the more technical medical studies be begun. Moreover, for securing the due familiarity with medical daily work (the need of which is often felt most sorely by many a fully-qualified practitioner fresh from the wards of a hospital, when called to his first cases of measles, chicken-pox, or scarlatina), and the tact which is so useful and necessary in visiting the sick, a year's pupilage or assistancy is advisable; but in our opinion this should be deferred to either just before or just after the student is qualified. In repeating this advice, we are at variance with many good authorities on medical education, who argue that acquaintance with minor surgery and pharmacy cannot be made too early in the career of the medical student, and so urge an apprenticeship by every student to a general practitioner as a first step. On the whole, probably a pupilage for a year with the house-

Digitized by Google

surgeon of a county hospital or provincial infirmary, in addition to some honest work in chemistry, physics, and biology, is the best plan of commencing medical studies. Entrance into the profession is thus made more gradual, and it can be more readily abandoned, with less sacrifice of time and money, should the pupil form a matured dislike to the necessary studies and work, or be incapable of pursuing them with advantage.

Every medical student should obtain an adequate acquaintance with the various departments of general science after he has passed his examination in Arts, and before he commences his purely technical studies. The natural sciences are so closely interwoven with medical progress that no student can now be considered well educated who does not possess an acquaintance with them. It is better if such a knowledge be gained before entrance at a medical school; but if this has not been done, a large part of the student's first year's study must be devoted to this object. The superiority of a university career is mainly due to the insistence of the authorities on this desideratum, and many of the corporations—notably the Royal College of Physicians of London—now make it a prominent feature of their first professional qualification; whilst those bodies who do not urge its importance are sure to suffer in public esteem and professional reputation for their lukewarmness in this respect. Chemistry, physics, and biological science are gradually being removed from the list of strictly professional to that of preliminary subjects; and every qualifying body is drawing nearer and nearer to this ideal, so that the work of the student will be proportionately lightened, and his after-success rendered more certain. A student who cannot grasp the chief principles of these sciences will but seldom master the theories and practice of the exclusively medical sciences and technics, and is at a corresponding disadvantage throughout his course of study and in his subsequent career as a physician or surgeon. Passing a preliminary examination in Arts should therefore be followed as soon as possible by passing the examination in Science which may be appointed by the examining body before which the student intends to present himself for a qualification or degree.

The next step is the commencement of his purely technical education. Anatomy and physiology should occupy eighteen months at least, and a summer session must be devoted to materia medica. It is a question of some difficulty as to whether a student should devote any of his time at this period to hospital work, and if so how much. There can be no hesitation as to his unfitness for any ward duties; and we are inclined to think that he will be better employed in the dissecting-room and in the class of practical physiology than in the out-patient rooms of the hospital. The practical hints gained by attendance on the out-patient surgeons—for the student at this stage of his career can learn nothing useful in medical practice—are easily acquired at a later period, and too much time cannot be spent in the attainment of a thorough knowledge of the two great sciences of anatomy and physiology, on which his future art and practice must be based. Practical anatomy, so far as the grosser structures are concerned, has long been well taught, and now in every well-equipped medical school a thorough instruction is imparted in practical histology, in the use of the instruments employed in physiological experiment and research, and in physiological chemistry. The methods by which the great principles of the laws of healthy action have been determined must be clearly understood, and it is only in late years that such an expression as "practical teaching in physiology" has had for the student any definite meaning. The coarser anatomical dissections, which were alone known to the student of fifteen years ago, have been supplemented by the finer histological methods and preparations, and the advance in this direction has been so great that a student is now expected to prepare and describe tissues which were then seen only as museum specimens prepared by an industrious and expert demonstrator or anatomical assistant. The length of time devoted to practical anatomy varies at the different boards, but less than two winter sessions are useless; and for the acquirement of the details, a third winter session, when practicable, is of great advantage. Many students return to the dissecting-room after they have had some hospital work, and are then well able to superadd a knowledge of anatomical detail to their medical and surgical experiences. Practical work in physiology is not insisted on by some examining bodies, but this will soon be altered if these corporations be animated by any desire that their qualifications should be held in esteem by future students and teachers. It is generally at this period of the curriculum that the medical student complains of being overworked, and is almost in despair of eventual success. This is largely due to the manner in which the various licensing bodies have framed their regulations. Every authority has laid down its own regulations in total disregard of those required by other boards. Whilst the student is endeavouring to master his anatomy, physiology, and materia medica, he finds that attendances on courses of lectures on chemistry and botany are still enforced even by bodies which do not examine in these subjects, whilst other bodies which examine stringently in them are contented with certificates merely showing that the candidate has received some instruction therein, and that such a certificate may be signed by any capable teacher. If a preliminary examination in Science were made compulsory, as the examination in Arts now is, all these contradictory and vexatious regulations might be swept away, and the student could then obtain his scientific training in any provincial town; for good teachers in those subjects are no longer limited to recognised medical schools. There is no reason whatever but the existence of these regulations for the attachment of science teachers to the smaller medical schools, which are thereby hindered in developing the clinical side of their teaching. Again, whilst some authorities insist on two years' attendance on clinical lectures in medicine and surgery, others are content with nine or even six months, and one body—the Royal College of Physicians of Edinburgh—only insists on clinical surgery for three months. One of the greatest benefits to the student of a one-portal system would have been the reduction of these chaotic regulations to a definite and well-considered scheme of medical education. The regulations of most of the examining boards are no longer in proper relation with modern scientific and practical teaching, and require revision. They are, in the main, relics of a bygone age, to which, in some instances, a little modern patching has been added;

Digitized by Google

in others they remain as they existed twenty or thirty years ago.

By the end of the second academical year the student should have passed his first professional examination in anatomy, physiology, and materia medica. When this is accomplished he should devote himself wholly to the real object of his study—a good knowledge of the principles of medicine, surgery, and therapeutics, and every care should be taken to secure a facile expertness in the use of the various instruments used for the detection and treatment of diseases in the daily practice of medicine, surgery, and midwifery. A student should now spend the greater part of his time in the wards, and should always strive to obtain in-patient dresserships and clerkships and similar offices. The more numerous and varied of these appointments he can hold, the better for his subsequent practice. At this period of his career it is usual for the student to attend lectures on medical jurisprudence, pathology, and hygiene. The two former subjects are compulsory, whilst the latter is made optional by most bodies. We have never been able to see the necessity of a course of lectures on such an *olla podrida* as forensic medicine; whilst pathology, to be of any value, should be essentially practical, and is the proper continuation of the course of practical physiology. In the best schools practical courses of pathology are given on these lines, but until the regulations of the examining bodies are altered the student must still attend the theoretical lectures, although he need have no practical instruction. Coarse morbid anatomy must be studied in the post-mortem theatre and the pathological museum, and the necessity of embracing every opportunity of increasing his knowledge in this branch is the more urgent, as the occasions which are presented to the general practitioner to revive his acquaintance with post-mortem appearances are necessarily very few. Moreover, it is only by a thorough conversance with the morbid processes and the changes effected by disease that a scientific and proper treatment can be established and carried out. In the last years of a student's career he should make every endeavour to secure a resident appointment at a hospital, for this will enable him to gain a familiarity with the immediate treatment of accidents and emergencies, and give him a sense of responsibility which such an experience alone can furnish. The readiness of resource and the calm discretion which never desert the able physician and surgeon have usually been acquired by filling one of these appointments. The study of mind disease is important, and attendance on the practice at a lunatic asylum is also of great value.

In tracing this outline of the proper course of study for a medical practitioner we have referred to no specialties, for we are strongly of opinion that every student should become as familiar with the diagnosis and treatment of the ordinary forms of disease affecting the eye, ear, throat, and skin as with those affecting the lungs, heart, or digestive organs. He should be as well able to use an ophthalmoscope, ear-speculum, and laryngoscope as a catheter or a clinical thermometer. No hospital staff discharges its duties to the students efficiently unless proper teaching in these subjects is secured for them, and an important reform would be effected if more care were taken to prevent students becoming qualified who had neglected these branches. After the student has obtained his qualification, it would be of lasting service and a source of much pleasure to him in after life if he could spare a year for increasing his acquaintance with these more special departments of our art, and, if possible, this year should be spent abroad. Paris and Vienna give greater facilities for studying many forms of disease, and for obtaining short courses of instruction in specialties, than perhaps any other cities in Europe or America. By this means, too, a fair knowledge of French and German may be acquired, and the importance of being able to converse and read in these languages is daily becoming more and more evident to the practitioner who desires to keep abreast of medical discoveries and to be acquainted with the theories on which the progress of medicine and surgery are dependent. The names of KOCH, PASTEUR, and LISTER prove that advances in medical science belong to no one country, and that the relations of our art and science are less insular now than at any other period in their history.

Before concluding this address on medical education, we would add a few remarks on our medical qualifications and degrees. The layman, and even the student, is often hopelessly ignorant of their meaning and relative value. At the University of Oxford a degree in Arts must be, and at Cambridge usually is, taken as a preliminary to the medical degree, but as this can be obtained by passing a previous examination in classics and mathematics, and then going out in Natural Science (some of the subjects being part of the series in the medical curriculum), there is very little difference in method or even in time between these universities and those which have separate preliminary examinations in Arts and Science, as the University of London, the Victoria University, and the Scotch Universities. The examination in Arts at the London University is spread over a most extensive range, and the Scientific Examination is unnecessarily severe. The papers in physics are especially open to this criticism; and as under the new regulations this examination must be passed previous to the commencement of medical studies, and is only held once a year, a candidate should do all in his power to minimise the possibility of rejection even in one subject, for this will probably act as an effectual barrier to his again presenting himself at this university, and all opportunity of obtaining the degree be lost through this mischance. The University of Durham and the Irish Universities have no separate examinations in science; chemistry and botany are included in their first professional examination, but they should be kept distinct. Higher examinations in Arts and Science are the essential differences between the degree-giving and the mere qualifying bodies, the standard in technical subjects being quite as high in some of the examining boards as at some universities, whilst the enforced curriculum is practically the same. The proposed fusion for examination purposes of the Colleges of Physicians and Surgeons of London will probably lead to their conjoined qualifications being considered the general qualifications of the modern English practitioner; and they will gradually supplant the older M.R.C.S. and L.S.A. qualifications. The well-known severity of the examinations in anatomy, physiology, and surgery at the College of Surgeons, and in chemistry, materia medica, midwifery, and medicine at the College of Physicians, affords an ample guarantee that everyone who obtains this double qualification has

Digitized by Google

thoroughly good knowledge of his profession; indeed, from a practical standpoint it is quite equal if not superior to the degrees of some of the universities. The facilities for obtaining degrees in Scotland are so abundant that students who merely obtain qualifications in that country may themselves open to some suspicion of idleness or want of ability to attain the higher honour. The amount of practical work insisted on by these bodies is very insufficient, and contrasts badly with the English and Irish regulations. A practical injustice is experienced by the metropolitan student in the fact that the same amount of industry and intelligence applied to the same course of study will only give him a qualification in London, which in the north of England (Durham) and in Scotland would obtain for him a degree. The University of London does not concern itself with the average medical student.

Diligence, properly trained intelligence, and health are the only essentials for the successful pursuit of medicine; but it must always be remembered that they are essentials, and that without them a satisfactory progress in medical studies is unattainable. The sage aphorism of the Greek master—"Life is short; art is long"—is even truer in our day than it was in his.

MEDICAL STUDENTS AND LEGISLATION.

IN our Address to Students last year we were tempted to say, "Fortunately, the days of single and incomplete qualifications are now numbered; the Legislature itself deems the evil one to be crushed." At that time everything seemed most promising for the passing of a Medical Act which would secure a one-portal admission to our profession, and we had hoped that this year we should have been able to congratulate those who were entering the profession on a change which would have simplified their curriculum of study and made it uniform in the three divisions of the kingdom. We also hoped that we should have had to point out the alterations in the method of study which the new departure would have caused, and the modifications which would have been necessary for those who were desirous of higher qualifications. But all such anticipations have been cruelly disappointed; the press of political questions, the cumbrous working of the parliamentary machine, and the opposition of some of our own corporate bodies, have effectually destroyed a well-conceived scheme for getting rid of our present confusion in medical qualifications.

"Where are we now?" medical students may be ready to ask as regards the prospects of medical legislation. "What are we to do? By what body shall we be examined when our curriculum is complete? Is there any chance of getting a complete diploma, the respectability of which shall be above dispute?" In answer to the fundamental question "where are we now?" our answer would be, "Very much where your predecessors were ten years ago." It is true that a Royal Commission has condemned utterly the existing system, and that the action of certain bodies as examining boards has been severely noticed in the Report of the Commissioners. But it is not less true that, except to sanguine minds, there is no immediate prospect of any satisfactory legislation to enforce what is so much needed—viz., completeness of diplomas, a reduction of the number of licensing authorities from twenty to three, and a fair guarantee of equality in corresponding examinations in England, Scotland, and Ireland. What Sir DOMINIC CORRIGAN called the "Battle of Shops" is suspended when the "shops" are about to be reformed. They then stand shoulder to shoulder, and in Parliament at the last moment advantage is taken of the period of the session, or the obstructive forms of the House, to raise new questions, and often petty questions, which simply strangle the Bill or compel the Government to yield on vital principles. This is the more easy nowadays when nothing excites the interest of the House of Commons but a big Franchise Bill or a strong party question. A mere Medical Bill that aims at giving the public better doctors, and students fairer examination and complete diplomas, is too unsensational to be interesting.

Another unfortunate feature in the situation is the determination of Scotland and Ireland to override England in this matter, to refuse guarantees to England such as in the opinion of the Royal Commission are necessary for securing fairness and equality in the examinations of the different divisions of the country. Medical education and the granting of diplomas and degrees are to Scotland a matter of pounds, shillings, and pence; and in the recent session, even the Scottish Universities, under the unfortunate guidance of Sir LYON PLAYFAIR, receded from their dignified support of the fundamental principle of the Government Bill.

There seems little immediate prospect of any effective legislation. The glass houses will help to hold each other up. They will effect voluntary combinations in each division of the kingdom, which will be satisfactory only to those having their "interests" in the *status quo* in that division. Mere voluntary conjoint boards, dictated by interest and "trade" considerations, afford no security against that degrading competition which has brought discredit on certain bodies, which we need not name. Meantime we advise students to aim steadily at taking their diplomas and degrees in that division of the kingdom in which they mean to practise. While all attempts to gain international guarantees are foiled, it is safest and most honourable to hold the right of practice from that division in which one has to work. In this way only is disparagement to be refuted, and a better and fairer state of the law to be gained.

THE CHOICE OF A TEXT-BOOK.

THE question which the student is always asking, and naturally, is what book will best serve his purpose in preparing for such or such examinations. The answer to this question is one which becomes every year more difficult. The number of medical text-books of a high class is now very great; therefore to select a few from amongst them may seem invidious. At the same time a list, which by no means pretends to be exhaustive, can be drawn up that may prove of value as a guide to the student in his choice. As representing all the various examining bodies, we may take for this purpose the three London centres—the College of Surgeons, College of Physicians, and the University of London.

COLLEGE OF SURGEONS EXAMINATIONS.

For the Primary Membership Examination at the College of Surgeons the subject of *Anatomy* may be well studied in GRAY'S Anatomy, ELLIS'S Demonstrations, or HEATH'S

Digitized by Google

Practical Anatomy; and in osteology specially may be mentioned the works of WARD and HOLDEN. The anatomical plates of ELLIS and those of GODLEE are very useful in supplementing practical work. In *Physiology* the books most to be recommended are KIRKES' Handbook, G. YEO'S Text-book, and H. POWER'S Elements; and *Histology*, apart from the sections devoted to it in the works of GRAY and KIRKES, may be read in KLEIN'S Elements. For the Primary Fellowship there may be read in addition (especially its histological and embryological sections) QUAIN'S Anatomy, which is the most complete and comprehensive in our language, FOSTER'S Text-book of Physiology, and GEGENBAUR'S Comparative Anatomy. Professor FLOWER'S Osteology of the Mammalia might also be read. For the Pass Examination (Membership) in the subjects of *Surgery and Surgical Anatomy* there are the text-books of BRYANT, HOLMES, and ERICHSEN'S work, so ably and learnedly edited by MARCUS BECK, the Practical Handbooks of BERKELEY HILL, CHRISTOPHER HEATH, and TREVES' Applied Surgical Anatomy. For *Surgical Pathology* PEPPER or BILLROTH may be recommended; in *Diseases of the Eye*, LAWSON or NETTLESHIP. For *Medicine and Midwifery*, *vide* College of Physicians, *infra*. For the Pass Examination (Fellowship) wider reading will be useful, and ERICHSEN'S work may be supplemented by chapters in the System of Surgery edited by HOLMES and HULKE. In *Operative and Practical Surgery* there are works by STIMSON, FERGUSSON, and S. SMITH, and HEATH'S Atlas. PAGET'S or BILLROTH'S Surgical Pathology and ZIEGLER'S Pathology may be profitably read in connexion with works mentioned under the Membership Examination.

COLLEGE OF PHYSICIANS EXAMINATIONS.

The subjects included in the various examinations for the licence of the College of Physicians, in addition to those which are also required by the College of Surgeons, comprise the following:—*Chemistry:* ROSCOE'S Elementary Chemistry, and ATTFIELD'S work. *Chemical Physics:* FOWNES' Inorganic Chemistry, edited by WATTS. *Botany:* OLIVER'S Elementary Botany; BALFOUR'S, or BENTLEY'S, or THOMÉ'S book. *Materia Medica and Therapeutics:* The works of MITCHELL BRUCE, GARROD, FARQUHARSON, and RINGER. *Medical Jurisprudence:* Those of GUY and TAYLOR. *Public Health:* WILSON. *Medicine:* ROBERTS, BRISTOWE, CARTER, and CHARTERIS. *Clinical Medicine:* FENWICK, FINLAYSON, and GRAHAM BROWN. *Pathology:* GREEN, COATS, and ZIEGLER (MACALISTER'S translation), and WOODHEAD'S practical work.

UNIVERSITY OF LONDON EXAMINATIONS.

For the Intermediate M.B. Examination of the University of London, the subject of *Organic Chemistry* may be studied in the text-books of WILLIAMSON and of FOWNES. *Materia Medica*, besides the books above mentioned, is more fully treated in the works of PHILLIPS, BARTHOLOW, and H. C. WOOD. *Physiology*, as for the Primary F.R.C.S., with perhaps the addition of such books as that of POWER and HARRIS for practical work, and of SCHAFER for practical histology. The anatomical text-books are those recommended for the College of Surgeons. For the M.B. Examination, the subject of *Medicine* may profitably be further studied in NIEMEYER'S Text-book, in that of AUSTIN FLINT, in some of the articles of QUAIN'S Dictionary or REYNOLDS'S System of Medicine, and in TROUSSEAU'S Lectures. Special monographs (see M.D.) may also be consulted. *Pathology*, which should be worked at practically, may be studied in GREEN'S, COATS', or ZIEGLER'S text-books; and also in the works of WILKS and MOXON, and CORNIL and RANVIER. *Midwifery*, in the writings of PLAYFAIR, LEISHMAN, LUSK, and BARNES; *Gynæcology*, in those of GALABIN, LOMBE ATTHILL, EDIS, and BARNES. *Dermatology*, in the text-books of TILBURY FOX, LIVEING, DUHRING, and M. MORRIS. *Medical Electricity*, in DE WATTEVILLE or POORE. *Medical Ophthalmoscopy*, in GOWERS' handbook. For the M.D. Examination the candidate will do well to extend his reading to the better known monographs, such MURCHISON on Continued Fevers and on Diseases of the Liver; ROSS, CHARCOT, and WILKS on Diseases of the Nervous System; BALFOUR, BYROM BRAMWELL, and WALSHE on Diseases of the Heart; POWELL and WALSHE on Diseases of the Lungs; W. ROBERTS and DICKINSON on Diseases of the Kidney. He will also have to dip into the works of BAIN, MILL, and JEVONS to prepare for the subjects of Logic and Mental Philosophy, included in this examination.

In the foregoing lists we have mostly indicated more than one work upon a subject; but it is, of course, impossible to indicate precisely a single work when so many exist. A certain amount of choice must be left to the student himself, who will do well to be guided in his final selection by the opinion of his teacher in the particular subject.

THE POOR-LAW MEDICAL SERVICE.

CAN we recommend the Poor-law Medical Service as a field for newly-fledged medical men? Before answering this question, using a phrase of the schools, "we must distinguish." The Poor-law Medical Service may be divided into two branches: (1) The workhouses and dispensaries, conducted on sound principles. (2) The Poor-law appointments, held under the old *régime*, which violate even the laws of justice. The first class finds examples in such infirmaries as Marylebone (London), Crumpsall (Manchester), and in the public dispensaries established in London, Birmingham, and other large cities and towns. At these large infirmaries an honest attempt is made to carry out fully hospital principles. There are resident surgeons, assistant surgeons, dispensers, paid nurses, and a complete hospital *personnel*. Besides Marylebone and Crumpsall, there are many other Poor-law infirmaries, which may be placed on a level with our subscription hospitals. What are the emoluments enjoyed by the medical superintendents of these institutions? The honoraria vary, for principal medical officers, from £200 to £500 a year. Marylebone is put down in the Medical Directory at £500; Shoreditch at £300, with apartments, rations, and washing; Leeds at £300, with residence; Birmingham at £250; and Greenwich at £250, with residence and rations. The assistant medical officers have usually salaries of £100 a year, with residence and rations.

The opportunities for studying all branches of medicine in a large workhouse are unrivalled. Every form of disease, and especially rare diseases, are therein to be found. We use the word medicine in its widest sense, necessarily including surgery, so that surgical experience is equally to be gained. We have only to point to the work done by ALEXANDER at the Liverpool workhouse, to impress this

Digitized by Google

truth on our young readers. Any young qualified practitioner, fond of his profession and devoted to scientific pursuits, will find in these hitherto neglected institutions a field which, if he has ambition and talent, may enable him to rival CHARCOT and PASTEUR. The Salpétrière at Paris is only a large workhouse. What CHARCOT has done there is now matter of history, and should be known to every medical student. We therefore must recommend such appointments. They possess another advantage—the discipline of life may be there learnt. Habits of command, and of dealing with a large number of persons, are acquired. There is room for the display of tact, kindness, and skill. There is a necessary degree of friction in such establishments, and such friction has a certain beneficial influence on character. The young practitioner must not expect to find therein a bed of roses, nor will he find life one; but if gifted with a moderate share of common sense, he will be able to pass a few pleasant and useful years in this official occupation, and in after-life turn to good account the various lessons learnt therein. There are also workhouses which have non-resident medical officers, whose salaries vary from £50 to £200 a year, all drugs and medical appliances being found. These appointments are very numerous, and are sought for because private practice is at the same time allowed. We need hardly say that we would advise any young qualified medical man to accept such an appointment if he can obtain it. They are thrown open to competition, and though personal considerations occasionally influence such appointments, as a rule, in England, the elections are based on the candidates' merits and qualifications. All appointments are only worth what the man himself can make out of them, and it entirely depends on a workhouse medical officer as to what position he will hold with his own profession, the guardians, and the public. This is an axiom we cannot too strongly impress on young practitioners.

Besides the union infirmaries there are dispensaries, the salaries of which vary from £100 to £130, all medicine and appliances being found by the authorities. These appointments are very useful to young practitioners who have no private means. They form a nucleus for the building up of private practice, though there are certain drawbacks in connexion with them. The dwellings of the poor are not very attractive; for men who are very fastidious, the noisome court, the foulsome alley, the overcrowded, broken-down tenement, do not present a pleasant picture; and the wind that comes between their nose and their nobility is not always scented with the perfumes of Arabia.

The training of medical men renders them familiar with unpleasant scenes and odours. Their mission is to cure and relieve disease wherever found, and it is unfortunately amongst the poor that we have the maximum of disease. For those who are prepared to work, the Poor-law dispensaries offer a wide field for activity, and those who work honestly and conscientiously amongst the poor will be sure to reap their reward. Medical men are submitted to a rigid censorship by the public, and this censorship is exercised without their knowledge, so that the men who are devoted to their duties are noticed and their work appreciated. Respectability is a word often misapplied. Some young practitioners may imagine that it is more respectable to be connected with a voluntary dispensary, where medical services are unpaid. The class of work in institutions of this kind very closely resembles what is done in the Poor-law dispensaries. Respectability was once defined by a witness in a court of law in this wise. A counsel asked whether a certain person was respectable. The answer came that he was. "But how do you know this," retorted the counsel. "Why, he keeps a gig." The same kind of reasoning makes the difference between the honorary surgeon of a voluntary dispensary and the paid surgeon of the State dispensary. Respectability does not consist either in keeping a gig or holding any class of appointment. Something more is required; so that our young friends must not be deterred by a shibboleth from entering into a service in which they can gain both pecuniarily and scientifically.

We must now briefly allude to the second class of Poor-law appointments. Under the old tender system surgeons contracted for the treatment of the sick poor. Remnants of this custom still exist, though the tender systems has been abolished. Excessive competition has effected in many parts of England such a reduction of salaries that the worst evils of the tender system are preserved and the sick poor as much neglected. There are numerous Poor-law appointments, the salaries of which vary from £12 to £50 a year, and out of such salaries the medical officers have to find all drugs, medical appliances, &c. We have so often spoken of the injustice to the sick in such arrangements that we need not again repeat our strictures. It is a moot question as to who is the most to blame—the Local Government Board, the guardians, or the medical officers. It is known to the authorities that under such circumstances the sick poor cannot receive adequate medical attendance. The medical officer cannot afford to give away medicine. He cannot discharge his duties conscientiously, and such a system is a mere farce. These appointments may be taken by very needy men, and the poorer the men the worse is it for the sick poor. We need hardly say, then, that we would not counsel any young practitioner to accept an appointment the duties of which he could not conscientiously perform.

We trust that with the progress of the educational influences now being brought to bear upon those who are connected with hospitals and other public charities, the proper and efficient treatment of the sick poor will be embraced in a comprehensive scheme, which will place union infirmaries and dispensaries in their proper position as State-supported institutions of the utmost importance to the well-being of society, and therefore worthy of taking rank with our voluntary hospitals and dispensaries.

ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

THERE are three branches of the public service in which the appointments are open to the profession by competitive examination—the Army, the Navy, and the Indian Services. The examinations take place twice a year, in February and August; the number of appointments to be made varies according to the requirements of the service, but is stated in the advertisements notifying the date on which the examinations are to be held. To be eligible to compete candidates must hold the double qualification to practise medicine and surgery, must be registered under the Medical Act, and must not be under twenty-one nor above

Digitized by Google

twenty-eight years of age. The public service holds out considerable inducements to young men, either as a temporary or permanent career. In the former point of view they are offered the means of passing a few years in a pleasant manner, with the advantage of seeing a good deal of the world, and with the right to retire into private life whenever they see fit, with a gratuity in case they have completed ten years' (or in the Navy eight years') full pay service. The advantages attaching to it as a permanent career are the receipt, from the commencement, of an income sufficient, with moderate care, to cover all ordinary expenses, the certainty of an increase to this after stated periods of service, the prospect of promotion to the higher ranks, carrying increase of pay and position, the right to retirement after twenty years' service on a pension for life, varying according to the rank which has been attained and the length of service on full pay, and a pension to widow and children varying according to the rank of the officer. But while these advantages are common to all three branches, there are differences which may exercise an influence in determining students for which they will decide to compete. In the Army there is the advantage of a certain amount of service at home and in temperate climates, the length of each tour of foreign service being restricted to five years; while in the Indian Medical Department the whole service must be performed in India. But, on the other hand, there are lucrative civil appointments open to a certain number of the Indian medical officers, and they have a right to retire, if they desire it, at an earlier period, and, when holding administrative rank, with a higher rate of pension than from the Army. The Naval Medical Service has certain advantages and drawbacks attached to it. The officer, on appointment, draws for the first four months a higher rate of pay than the others, but he loses the great advantage of the full course of instruction afforded at Netley. He is also liable, when his ship is paid off, to be placed on half-pay till he gets another, though this, we believe, is at present obviated by employing him in one of the naval hospitals. When it is in operation, however, it forms a very serious drawback, as the period passed on half-pay does not count as service towards the right to pension. In all three branches the surgeons are promoted to higher rank after twelve years' service, but are required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers. In the Army and Indian Services this examination may be passed at any time between the fifth and tenth year of service; in the Navy after the completion of eight years from the date of entry. The promotions to the administrative ranks are made by selection; but in the Army and Indian Service Surgeon-Majors must pass an examination, chiefly on matters connected with administrative duties, before they are eligible to be selected. The examination is optional, but an officer who does not choose to undergo it cannot be promoted.

We have thought it well to call the attention of students to these special points in connexion with the public service, and would refer them for the details respecting the course of instruction at Netley and the rates of pay, half-pay, and pension to a subsequent part of this number.

SESSION 1884-85.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council,[1] and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, and shall enter therein the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent — have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before Dec. 31st, in each year, to the registrar of the General Council, who shall as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Act (1858), and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation.

Pursuant to resolutions passed by the General Medical Council at its session in July, 1880, the Regulations for Preliminary General Education, which took effect from January 1st, 1882, are as follows:—

No person shall be allowed to be registered as a medical student unless he shall have previously passed a Preliminary Examination in the subjects of General Education as specified in the following list:[2] — 1. English Language, including

[1] Exception may be made in the case of a Student from any Indian, Colonial, or Foreign University or College, who shall have passed the Matriculation or other equivalent Examination of his University or College, provided such Examination fairly represents a standard of General Education equivalent to that required in this country.

[2] The Examinations in General Education conducted by Universities will be accepted as heretofore, but if in any of these Examinations the subjects of Elementary Mechanics of Solids and Fluids are not included, a knowledge of these subjects will be required at a subsequent Examination.

Digitized by Google

Grammar and Composition.[3] 2. English History. 3. Modern Geography. 4. Latin, including Translation from the original and Grammar. 5. Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first two books of Euclid or the subjects thereof. 6. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics.[4] 7. One of the following optional subjects: (*a*) Greek; (*b*) French; (*c*) German; (*d*) Italian; (*e*) any other Modern Language; (*f*) Logic; (*g*) Botany; (*h*) Elementary Chemistry.

Communications relating to the Medical Students' Register, or to the registration of medical students, should be sent to the registrars, to the following addresses:—

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W. — Archibald Inglis, M.D., Registrar of the Branch Council for Scotland, 33, Albany-street, Edinburgh. —R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS OF THE MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

A student desiring to graduate in Medicine must pass the requisite examinations for the degree of B.A. He must afterwards spend two years in study[5] prior to the first or scientific examination for the degree of Bachelor of Medicine, and two years more, after passing the first, prior to the final or practical examination for the same degree.

Every student must reside in one or other of the Colleges or Halls, or in licensed lodgings, for three years, passing at least two examinations in Arts, and one in either Mathematics, Natural Science, Law, Modern History, or Theology, when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honour, he has to pass a third examination *in Literis Humanioribus*.

There is an examination in State Medicine and Public Health, to which Bachelors of Medicine of the University are admissible.

A dissertation has to be publicly read, three years after obtaining the M.B., before being eligible for the M.D.

The study of Natural Science is carried on at the Museum, in which are extensive opportunities for the study of Physics, Chemistry, General, Comparative, and Human Anatomy, Histology, and other departments of Natural Science, together with courses of lectures and of practical instruction by the several professors. There is in the medical department a pathological series, including the collection of Schroeder Van der Kolk, and a sanitary laboratory. The Radcliffe Library, containing above 40,000 scientific volumes, is open to all students daily from 10 till 4, and on certain evenings during term. There are lectures and practical instruction in Botany at the Botanical Gardens, and clinical instruction at the Infirmary.

The medical examinations take place every year in the Trinity (summer) term. Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other colleges, by competitive examination in Natural Science. Every year a Radcliffe Travelling Fellowship is competed for by any who, having taken a first class in any of the schools, or having obtained a University prize or scholarship, propose to study Medicine. The Travelling Fellows receive £200 a year for three years, half this period being spent in study abroad.

More detailed information may be obtained from the University Calendar; from the Students' Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; from E. Chapman, Esq., M.A., Frewin Hall; and from the Sub-Librarian in the Radcliffe Library at the Museum.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may be done, and should if possible be done, immediately on coming into residence, or, which is best, through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study, and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes.

The expenses of residence, lectures, &c., at a College are about £150 per annum; but these are in many cases lessened by Scholarships, ranging in value from £20 to £80 a year, which are very numerous, and obtainable by most students of industry and ability. They are chiefly given for mathematical and classical proficiency.

Non-collegiate students can reside at less expense (£80 or £90 a year) than those who enter a College. They are allowed to attend certain of the College lectures and all the professors' lectures, and have the same University status and privileges as the other students. Cavendish and Selwyn Colleges have been recently founded to afford facilities for obtaining a degree at a moderate cost.

For the degree of *Bachelor of Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years only being then required, though it is rarely sufficient. This time may be spent in Cambridge or elsewhere. The earlier portion of it is usually spent in Cambridge, the student remaining in the University till he has passed the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite Lectures and Hospital Practice may be attended here, and some students remain to attend Lectures and Hospital Practice after they have passed the second examination for M.B.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These may be taken together or separately. The *second* in Human Anatomy and Physiology, and in Pharmacy and Pharmaceutical Chemistry. These may be taken together or separately. The *third* may be also taken in two parts—viz., (1) Principles of Surgery and Midwifery and Diseases of Women, and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, and Medical Jurisprudence. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. They take place twice annually (in June and December).

An Act has to be kept, which consists in reading an original thesis and passing a *viva voce* examination on the subject of the thesis and on other subjects.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations). Previously to the second examination, the student must have attended lectures on Human Anatomy, Pharmacy and Pharmaceutical Chemistry, Physiology, have Dissected for six months and attended Hospital Practice six months. Previously to the first part of the third examination, he must have attended lectures on Pathological Anatomy, the Principles of Surgery and Midwifery, the Surgical Practice of a Hospital with Clinical Lectures for a year, ten cases of Midwifery, and produce a certificate of proficiency in Vaccination. Previously to the second part of the third examination he must have attended Lectures on the Principles and Practice of Physic, the Physiological Action and Therapeutic uses of Drugs, and Medical Jurisprudence; also the Medical Prac-

[3] The General Medical Council will not consider any Examination in the English Language sufficient that does not fully test the ability of the candidate:—(1) To write sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (2) to write correctly from dictation; (3) to explain the grammatical construction of sentences; (4) to point out the grammatical errors in sentences ungrammatically composed, and to explain their nature; and (5) to give the derivation and definition of English words in common use.

[4] This subject may be passed either as Preliminary, or before, or at the first Professional Examination.

[5] If he have taken the higher honours in the Natural Science School he may go in for the first M.B. examination on the first opportunity, and so have a longer period of practical study before the second M.B. examination. The "testamur" of the Natural Science School exempts from examination in Physics and Chemistry at the first M.B. This examination, therefore, comprises in the cases of such candidates Anatomy and Physiology alone. By a recent decree candidates who have not passed the Natural Science School are allowed to take up Physics and Chemistry, only in the examination, before entering for the Anatomy and Physiology.

Digitized by Google

tice of a hospital with Clinical Lectures, and have been clinical clerk for six months.

The degree of *Doctor in Medicine* may be taken three years after M.B. An Act has to be kept, with *vivâ voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

The candidate for the examination for the degree of *Bachelor of Surgery* is required to have passed the *first* and *second* examinations, and the first part, of the *third* examination for M.B.; to have attended the Surgical practice of a hospital for two years, have acted as House Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery. The subjects of the Examination are Surgical Operations and the application of Surgical Apparatus, and the Examination of Surgical patients. Before *admission* to the degree he must also have passed the *second* part of the third examination for M.B.

For the degree of *Master in Surgery* the candidate must have passed all the examinations for B.C. two years. He is required to pass an examination in Surgical Anatomy and Surgical operations, Pathology, and the Principles and Practice of Surgery. A surgical case and a topic relating to surgery are submitted to him, on one or both of which, at his option, he is required to write a short extempore essay.

The examination for certificates in *Sanitary Science* by the University of Cambridge will begin on Tuesday, Oct. 7th. The names of candidates, who must be on the Medical Register of the United Kingdom, should be sent to Dr. Anningson, Cambridge, on or before Sept. 28th.

The following is a summary of the course which a student (commencing at the University, say, in October, 1884) may follow:—He enters at any one of the colleges, or as a non-collegiate student, and passes the Previous Examination (in Classics and Mathematics), in October, 1884, or in December, 1884, or in April, 1885, unless he has already passed the equivalent examination under the Local Examinations or the Oxford and Cambridge Schools Examination Board. He is then registered as a student of medicine, and pursues his medical studies in the University for a part or the whole of the period. Natural Sciences Tripos Examination (in Human and Comparative Anatomy, Chemistry, and Botany), in June, 1887; this admits to the B.A. degree in June, 1887. Second Examination for M.B. (in Human Anatomy and Physiology, and Materia Medica), June or December, 1887, or May, 1888. Third examination for M.B. (in Medicine, Surgery, Midwifery, and Medical Jurisprudence), November, 1889. Examination for B.C. Surgery, November, 1889. Degree of M.B. or B.C., November, 1889. Practically, however, more time than this is usually required.

Attendance at the hospital and the several lectures in the medical school is recognised by the Universities of Cambridge and London, and by the Colleges of Physicians and Surgeons.

Students should remain in Cambridge during the long vacation (July and August) and part of the Christmas vacation, as well as during the terms.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the third Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. Several scholarships, exhibitions, and prizes are associated with these examinations.

The *Preliminary Scientific* (*M.B.*) *Examination* takes place once in each year, and commences on the third Monday in July.[6] No candidate will be admitted to this examination until he shall have passed the Matriculation Examination, nor unless he have given notice of his intention to the registrar at least fourteen days before the commencement of the examination. Fee for this examination, £5.

Candidates are examined on the following subjects: Inorganic Chemistry, Experimental Physics, and General Biology. Candidates for Honours may also be examined in Botany and Vegetable Physiology, and Zoology, unless they have previously obtained an exhibition in any one of the subjects of this examination at the Intermediate Examination in Science, in which case they shall not be admissible to the examination for Honours in that subject.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University. 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[7] at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place once in each year, and commences on the last Monday in July. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least one year previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list:—Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Matriculation Examination, dissected during two winter sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry; in applying tests for discovering the adulteration of articles of the Materia Medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned), must be transmitted to the registrar at least fourteen days before the commencement of the examination. Fee for this examination, £5.

Candidates will be examined in the following subjects:—Anatomy, Physiology, Histology, Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all these subjects.

Any candidate who has passed the Intermediate Examination in Medicine in all its subjects at one time may be examined at the Honours Examination next following the Intermediate Examination in Medicine at which he passed for Honours in (1) Anatomy, (2) Materia Medica and Pharmaceutical Chemistry, (3) Physiology and Histology, and (4) Organic Chemistry. The examinations take place in the week following that in which the Pass Examination commenced. They are conducted by means of printed papers and practical work.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy, and the candidate who shall distinguish himself the most in Histology and Physiology, will each receive an exhibition of £40 per annum for the next two years; the candidate who shall distinguish himself the most in Organic Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, will each receive an exhibition of £30 per annum for the next two years. On receiving each quarterly instalment he must declare his intention of presenting himself at the M.B. Examination within three academical years from the time of his passing the Intermediate Examination in Medicine. Under the same circumstances, the first and second candidates in Anatomy and in Histology and Physiology, and the first candidate in Organic Chemistry and in

[6] Candidates for the Degree of M.B. are required after Jan. 1st, 1885, by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and are recommended to devote a preliminary year to preparation for it according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

[7] Candidates who pass the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their Professional studies, as heretofore, from that Examination.

Digitized by Google

Materia Medica and Pharmaceutical Chemistry will each receive a gold medal of the value of £5.

M B. Examination.[8]—The M B Examination takes place once in each year, and commences on the first Monday in November. Each candidate, two academical years after passing the First Examination, must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6 Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has exteded. The fee for this examination is £5.

Candidates will be examined in the following subjects:—General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all the subjects of examination.

Any candidate who has passed the M.B. Examination may be examined at the Honours Examination next following the M.B. Examination at which he has passed for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine they are conducted by means of printed papers, but the examiners will not be precluded from putting *vivâ voce* questions upon the written answers of the candidates.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine will receive £50 per annum for the next two years, with the style of University Scholar in Medicine. Under the same circumstances the candidate who shall distinguish himself the most in Obstetric Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Obstetric Medicine. Under the same circumstances the candidate who shall distinguish himself the most in Forensic Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine. Under the same circumstances the first and second candidates in each of the preceding subjects will each receive a gold medal of the value of £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the Examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most will receive £50 per annum for the next two years, with the style of University Scholar in Surgery. Under the same circumstances, the first and second candidates will each receive a gold medal of the value of £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.[9] 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University: (*a*) To Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University. (*b*) Or to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. (*c*) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *vivâ voce* interrogation.

Candidates will be examined in Logic and Psychology and in Surgery, and will not be approved unless they have shown a competent knowledge in both the subjects of examination.

If sufficient merit be evinced, the candidate who shall distinguish himself the most in Surgery at this examination will receive a gold medal of the value of £20.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. (*c*) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *vivâ voce* interrogation.

Candidates will be examined in Logic and Psychology and in Medicine, and will not be approved unless they have shown a competent knowledge in both the subjects of examination. If sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine at the examination for the M.D. degree will receive a gold medal of the value of £20.

Public Health.—A Special Examination will be held once in every year in subjects relating to Public Health, to commence on the second Monday in December. Candidates must have passed the second examination for the M.B. degree in this University at least one year previously; and must give notice of their intention to the registrar, at least *two calendar months* before the commencement of the examination. The fee for this examination is £5. Candidates will be examined in Chemistry, Microscopy, Meteorology, Geology, Physics and Sanitary Apparatus, Vital Statistics, Hygiene, and Sanitary Law. The examination will be both written and practical, and will extend over four days.

[8] Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations will be required to have also passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

[9] Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

Digitized by Google

Candidates will not be approved unless they have shown a competent knowledge in all the principal subjects of the examination. If sufficient merit be evinced the candidate who shall distinguish himself the most will receive a gold medal of the value of £5.

UNIVERSITY OF DURHAM.

A certificate, two licences, and three degrees are conferred—viz., a certificate of proficiency in Sanitary Science, a licence in Medicine, and a licence in Surgery; and the degrees of Bachelor in Medicine, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* there are two professional examinations, the first being held twice yearly—viz., in September (in 1884 commencing on the 22nd) and April (in 1885 commencing on the 20th); the second is also held twice yearly—viz., in December (in 1884 commencing on the 1st) and in June (in 1885 commencing on the 22nd).

The subjects for the first examination are—Anatomy, Physiology, Chemistry and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of having passed one of the following examinations in Arts: (*a*) the examination for graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), and Queen's College (Kingston); or (*b*) the Preliminary or Extra-professional Examination for graduation in medicine at one of the following universities—London, Edinburgh, Glasgow, St. Andrews, Aberdeen, and Queen's (Ireland); or (*c*) the Preliminary Examination in Arts qualifying for the membership of the Royal College of Physicians of London or for the fellowship of the Royal College of Surgeons of England; or (*d*) the Preliminary Examination in Arts for the degrees in medicine of the University of Durham (in 1884 commencing on September 22nd, and in 1885 commencing on March 24th and September 21st). (3) Of attendance on two courses of Anatomy, on one of Physiology, on one of Theoretical and one of Practical Chemistry, and on one of Botany; of twelve months' dissection; and of attendance on a course of Practical Physiology of not less than thirty lessons.

The subjects for the Second Examination are Medicine, Surgery, Pathology, Materia Medica and Therapeutics, Midwifery and Diseases of Women and Children, Medical Jurisprudence and Public Health. For it candidates must produce the following certificates—viz., (1) of being not less than twenty-one years of age; (2) of good moral character; and (3) of attendance on the remainder of the course of medical and surgical study as prescribed by the Royal College of Surgeons of England, together with the following additional subjects—viz., one course of lectures on Medicine, one on Therapeutics, one on Public Health, and one on Botany, and on Medical Hospital Practice, with Clinical Lectures, during one winter and one summer session.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-upon-Tyne.

For the degree of *Master in Surgery* the candidate must have passed the Examination for the degree of Bachelor in Medicine and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional paper on Surgery, and will have to perform operations on the dead body, and to explain the use of instruments.

For the degree of *Doctor of Medicine* candidates must be not less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical and surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the registrar of the College.

The degree of Doctor of Medicine, for Medical Practitioners of fifteen years' standing, without residence.—There is a special Examination, under the following regulations:—1. That the candidate shall be registered by the General Council of Medical Education and Registration of the United Kingdom. 2. That the candidate shall have been in the active practice of his profession for fifteen years as a qualified practitioner. 3. That the candidate shall not be under forty years of age. 4. That the candidate shall produce a certificate of moral character from three registered members of the medical profession. 5. That if the candidate shall not have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), an examination in Arts, he shall be required to pass an examination in Classics and Mathematics. 6. That if the candidate shall have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), a preliminary examination, he shall be required to translate into English passages of certain named Latin authors. 7. That the candidate shall pass an examination in the following subjects: *a*, Principles and Practice of Medicine, including Psychological Medicine and Hygiene; *b*, Principles and Practice of Surgery; *c*, Midwifery and Diseases peculiar to Women and Children; *d*, Pathology, Medical and Surgical; *e*, Anatomy, Medical and Surgical; *f*, Medical Jurisprudence and Toxicology; *g*, Therapeutics. 8. That the fee shall be 50 guineas. 9. That if the candidate shall fail to satisfy the examiners, the sum of 20 guineas shall be retained; but that if he shall again offer himself for the examination, the sum of 40 guineas only shall then be required.

Examinations in accordance with the above regulations will commence on Dec. 1st, 1884, and June 22nd, 1885, in the College of Medicine, Newcastle-on-Tyne.

Certificate of Proficiency in Sanitary Science.—Candidates for this certificate must be registered medical practitioners and have attended one course of lectures on Public Health, at the College of Medicine, Newcastle-on-Tyne, extending over one winter session. The examination will be by written papers, practical, and *viva voce*, and will commence on October 2nd, 1884, and on April 20th, 1885. In the practical examination the candidate will be required:—To report upon the condition of some actual locality, to analyse liquids and gases, to explain the construction and use of instruments employed in meteorology, and to make microscopic examinations. The fee is £5 5*s*.

Medical Officers of Health of five years' standing, who were registered as qualified members of the profession before January 1st, 1873, may obtain the certificate of proficiency in Sanitary Science under the following conditions:—They must be registered medical practitioners, and be not under thirty years of age; they will be required to pass the same examination as before-mentioned, write an essay upon some practical sanitary subject, and will be examined upon the essay and upon other sanitary questions. The fee is £10 10*s*.

VICTORIA UNIVERSITY.

Three degrees are conferred by the Victoria University—viz.: Bachelor of Medicine (M.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in Medicine and Surgery are required to have matriculated in the University.

Before admission to the degree of Bachelor of Medicine a candidate must produce certificates of four years' study subsequently to the date of his registration as a medical student, two of such years having been passed in a college of the University, and one year, at least, having been so passed subsequently to the date of passing the Preliminary Examination in Science. The subjects of this examination are, Chemistry, Inorganic and Organic; Zoology and Botany; Elementary Mechanics and Physics. The subjects of the Intermediate Examination for the degree of Bachelor of Medicine are Anatomy, Physiology, Materia Medica, and Pharmacy. The subjects of the final examination for the degree are Systematic, Practical, and Clinical Surgery; Systematic and Clinical Medicine, including Mental Diseases, Obstetrics and Diseases of Women and Children; Pharmacology and Therapeutics; General Pathology and Morbid Anatomy; Forensic Medicine; and Hygiene. The final examination is divided into two parts, which may be passed separately or together. The first part consists of an examination in Systematic Surgery, Pharmacology and Therapeutics, and General Pathology. Candidates are permitted to offer themselves for examination in these subjects at any time not prior to the completion of their third year of medical study. No candidate is admitted to the second part until he has completed his fourth year of study in accordance with the University regulations.

Doctor of Medicine.—No candidate can be admitted to this degree unless he has previously received the degree of Bachelor of Medicine, and at least one year has elapsed since he passed the examination for that degree. Candi-

Digitized by Google

dates are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine, or of some science directly relative to medicine. Candidates may be examined on any subject connected with their dissertation.

Master of Surgery.—Candidates presenting themselves for this examination are required to have graduated as Bachelors of Medicine in the University, and to pass an examination in Surgical Anatomy, Surgical Pathology, Practical Surgery, Clinical Surgery, and Ophthalmology.

The following fees are payable:—For matriculation, £2; for the Preliminary Examination in Science, £1; for the Intermediate Examination for the degree of M.B., £1; for the Final Examination, £2; for the examination for the degree of Ch.M., £2. A fee of £2 is payable on sending in the dissertation for the degree of M.D., £5 on the conferring of the degree of M.B., £10 on that of M.D., and £10 on that of Ch.M. No fee entitles the candidate to more than one examination.

UNIVERSITY OF EDINBURGH.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

No candidate is admitted to a professional examination who has not passed a satisfactory examination on at least two of the following subjects (in addition to the subjects mentioned above):—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philsophy; and the examination on these latter subjects also takes place before the candidate has entered on his medical curriculum.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.[10]

Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—(*a*) That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures;[11] Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery,[12] courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. (*b*) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (*c*) That he has attended, during a course of not less than fifty hours' instruction, the class of Practical Materia Medica in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted by a teacher recognised by the University Court; or that he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital or dispensary, by a member of a surgical college or faculty, a licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain. (*d*) That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary physician, a surgeon, or a member of the London or Dublin Society of Apothecaries.

Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (*a*) full winter courses on any two of the following subjects:—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (*b*) on one such course and two three months' courses on any of the following subjects:—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (*a*), attendance on a third course, although unnecessary to constitute an *annus*, will also be accepted. The other subjects and the additional courses, not given in London or Dublin, necessary for the degrees of the University, require to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance at a qualified hospital along with a course of Practical Anatomy. But in a provincial school where there are two or more lecturers recognised by this University, a second *annus medicus* may be made by attendance on at least two six months', or one six months' and two three months', recognised courses.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine a declaration in his own handwriting, that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master; together with a statement of his studies, accompanied with proper certificates.

Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; clinically on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

Students who profess themselves ready to submit to an examination in the first division of these subjects at the period of examination immediately preceding their second winter session of professional study may be admitted to examination at that time; provided always that students who commence their medical studies in the summer session shall not be admitted to a degree in Medicine unless their course of study, subsequent to the completion of the summer session in which they commence their medical studies, shall not be less than the minimum course of four years prescribed in Section 4 hereof.

Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the fourth examinations at the end of their fourth year.

If any candidate at these examinations be found unqualified, he cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects, either in the University or other medical school.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produces a certificate of

[10] No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

[11] Certificates of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the parts dissected, and the degree of care with which the dissections have been made. Students are recommended not to appear for an examination in Anatomy with a view to a degree until they have dissected the human body at least once.

[12] The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

Digitized by Google

having been engaged, subsequently to his having received the degrees of M.B. and C.M., for at least two years in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degrees of M.B. and C.M., or thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of M.B. and C.M., which he may have made a subject of study after having received that degree. The candidate must lodge his thesis with the dean on or before 30th April of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum for the Bachelor's and Master's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

Persons who began their medical studies before the 4th of February, 1861, are entitled to graduate under the system in force before or after that date, according as they may comply with the regulations in force in the University before or after that date.

Examinations on the preliminary branches of extra-professional education will take place on the 7th, 8th, 9th, and 10th October, 1884; and on the 10th, 11th, 12th, and 13th March, 1885.

The fees for M.B. and C.M. are £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D., and the stamp duty for the latter, must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education begin on the 8th of October, 1884, and on the 1st of April, 1885.

The fees for the degrees are the same as in the University of Edinburgh.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant-clerk of the Senate of the University.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10s.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions:—Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the Application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to Professor Brazier, Dean of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

Two degrees in Medicine are granted—namely, Bachelor of Medicine and Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly, towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. A portion of the graduation fee (viz., £10 10*s.*) shall be forfeited should the candidate fail to appear, or to graduate, at the time appointed. A satisfactory examination, written and *viva voce*, must be passed in the following departments—viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery, and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine* and *Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degree of Bachelor of Medicine and Master in Surgery will be under the following regulations: The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty, on or before the 25th of March in each year.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degre

Digitized by Google

and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Materia Medica and Pharmacy, and Descriptive Anatomy and Institutes of Medicine (Practical Histology and Physiology) previous to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B.A., or at any subsequent commencement. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures:—Anatomy, Practical Anatomy, Theory of Surgery, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy. Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College. Six months' instruction in Practical Midwifery, including Clinical Lectures. A certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections, three months' laboratory instruction in Chemistry, three months' Practical Histology, and one month's instruction in Vaccination are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Liceat ad Examinandum*, £5; for the M.B. degree, £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study, which includes the following additions to the courses named above for the M.B.: Operative Surgery, Two Courses of Dissections, Ophthalmic Surgery.[13] Candidates are required to perform surgical operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.[14]—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and Senior Fellows. Fee for the degree of Master in Surgery, £11.

University Licences.—Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine—The medical course and examination necessary for the Licence in Medicine are the same as for the degree of M.B. Fee for the *Liceat ad Examinandum*, £5; for the Licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the Licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5; for the Licence in Surgery, £5.

Qualification in State Medicine.—Doctors in Medicine or graduates in Medicine and Surgery of Dublin, Oxford, or Cambridge who wish to obtain from the University a Certificate of Qualification in State Medicine can do so on passing an examination in a limited course of the following subjects: 1. Law, comprehending sanitary legislation, and the laws relating to the conduct and duties of medical men. 2. Engineering in its sanitary aspects. 3. Pathology, including the laws of epidemics, vaccination, insanity, &c. 4. Vital and sanitary statistics. 5. Chemistry in relation to air, water, gaseous poisons, deodorisation, and disinfection. 6. Meteorology. 7. Medical jurisprudence. 8. Hygiene.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4*s.*); Medical and Surgical Lectures, £63 15*s.* 6*d.*; Hospitals, £44 2*s.*; Medical and Surgical Examinations and Degrees, £31.

[13] Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previous to the creation of the degree of Bachelor in Surgery.

[14] Masters in Surgery must be of the standing of Masters of Arts.

ROYAL UNIVERSITY OF IRELAND.

The following degrees are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Master of Surgery; in Obstetrics, a special diploma; in Sanitary Science, a special diploma. After the year 1884 all the Medical Examinations will be held twice yearly—viz., towards the end of April and in October.

The course for degrees in Medicine, &c., shall be one of at least four years' duration. All candidates for these degrees are, in addition to attending the lectures and complying with the other conditions to be from time to time prescribed, required to pass the following examinations: The Matriculation Examination, the First University Examination, the First Examination in Medicine, the Second Examination in Medicine, and the Degree Examination.

The First Examination in Medicine.—Students shall be admitted to this examination after the lapse of one academical year from the time of their matriculation. The subjects of this examination shall be:—Zoology, Botany, a modern language (either French or German). Candidates who have passed in a Modern Language at the First University Examination in Arts are exempt from again presenting this subject at the First Examination in Medicine, except as a qualification for admission to compete for Honours, the answering of the candidates in the three subjects above mentioned being taken into account in awarding Honours.

The Second Examination in Medicine.—Students shall be admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the First Period of the Course of Medical Studies. The subjects of this examination shall be:—Anatomy, Physiology, Materia Medica, Chemistry.

The Examination for the Degree of M.B.—Students shall be admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the Second Period of the Course of Medical Studies. The subjects of this examination shall be:—Anatomy, including Practical Anatomy; Physiology, including Practical Physiology; Histology; Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. Students who have commenced their medical studies since January 1st, 1884, must also produce a certificate of having been registered as Students in Medicine by the Medical Council for a period of at least forty-five months.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of two academical years from the time of obtaining the degree of M.B. Provided, however, that all persons who shall be students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the examination herein prescribed for the M.B. degree. Every candidate shall be examined at the bedside, and required to diagnose at least six cases, medical and surgical, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners, and to discuss all the questions arising thereon. Every candidate shall submit to the Medical examiners, for their approval, a thesis certified by him (or her) to have been composed by himself (or herself). No thesis shall be approved which does not contain some original or personal observations in practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

The M.Ch. degree shall be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Surgery, including Operative and Clinical Surgery.

The Diploma in Obstetrics will also be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Midwifery, and the use of Obstetrical instruments and appliances.

The Diploma in Sanitary Science will be conferred only on graduates in Medicine of the University. The exami-

Digitized by Google

nation shall embrace the following subjects:—Climate, Chemistry, Geology, Physics, Vital Statistics, Hygiene, Sanitary Law.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.

Licentiates.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in the manner prescribed by the General Medical Council. Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—1. Attending the practice of a hospital or other institution recognised by the College for that purpose. 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery. 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals.[15] Of having discharged the duties of a medical clinical clerk during six months; and of a surgical dresser during other six months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, Botany, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with Dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical study of Diseases peculiar to Women. Of having passed the professional examinations, of which there are three, each partly written, partly oral, and partly practical. The subjects of the first examination are:—Chemistry and Chemical Physics—viz., Heat, Light, and Electricity; Materia Medica; Botany and Pharmacy; and Osteology. The subjects of the second examination are Anatomy and Physiology. The subjects of the final examination are Medical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Medicine; Surgical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Surgery; Midwifery and Diseases peculiar to Women; Forensic Medicine; Public Health and Therapeutics.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery.

Members.—The members of the College, present and future, shall be alone eligible to the Fellowship. Every candidate (except such as are admissible under special provisions relating to practitioners) must produce proof of his having been engaged in professional studies during a period of five years. The examination will be partly written and partly *vivâ voce*. Doctors and Bachelors of Medicine may claim exemption from all or any part of the examination, except such as relate to the Third or Pass Examination. Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule A to the Medical Act and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exampt from re-examination on the subjects of the Primary Examinations. Any candidate who shall have obtained a degree in Surgery, at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of Study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

[15] A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE.

Professional Education.—The following are recognised modes of commencing professional education:—(1) Attendance on the practice of a hospital, or other public institution recognised by this College for that purpose. (2) Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. (3) Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates, viz:—Of having, prior to the commencement of professional study, been registered by the General Medical Council. Of having attended lectures on Anatomy during two winter sessions. Of having performed dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology[16] during one winter session. Of having attended a Practical Course of General Anatomy and Physiology[17] during another winter or a summer session, consisting of not less than thirty meetings of the class.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practices of Surgery, Medicine, and Midwifery, will be required to produce the following certificates, viz.:—Of being twenty-one years of age. Of having been engaged, subsequently to the date of registration by the General Medical Council, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on Surgery during one winter session. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 3.[18] Of having

[16] By the Practical Course referred to in Clause 3, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

[17] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[18] The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical

Digitized by Google

attended one course of lectures on each of the following subjects, viz :—Chemistry,[19] Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction), and a certificate of having personally conducted not less than ten labours, and Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study.[20] Of instruction and proficiency in the practice of Vaccination.[21] Of having attended, at a recognised hospital or hospitals, the Practice of Surgery, during three winter[22] and two summer[23] sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.[24] Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended at a recognised hospital or hospitals, clinical lectures on Surgery, during two winter and two summer sessions. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 9) demonstrations in the post-mortem rooms of a recognised hospital. Of having attended at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Special Notice.—Candidates commencing their professional education on or after the 1st of October, 1882, will not be admitted to the Second or Pass Examination until after the expiration of two years from the date of their passing the Primary or Anatomical and Physiological Examination for such diploma, except in the following cases:—When a candidate, before presenting himself for the Primary Examination, shall possess a recognised degree or diploma in Medicine or Surgery, or shall have completed the curriculum of professional education for the diploma. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the Primary Examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the Primary Examination for the Fellowship, it being required in such case that not less than one year of attendance on the Surgical Practice of a recognised hospital shall intervene between the date of his passing the Primary Examination for the Fellowship and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital and having completed a year of such attendance, shall fail to pass the Primary Examination at the end of his second winter session of attendance at a recognised medical school, provided that in his case not less than one year shall elapse between the date of his passing the Primary Examination and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. When a candidate owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the Primary Examination on the completion of his second year of professional study. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the Primary Examination on the completion of his second year of professional study, it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Professional Examination.—This examination is divided into two parts. The first or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery,[25] is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients.

The Primary Examinations are held in the months of January, April, May, July, and November, and the Pass Examinations generally in the ensuing week, respectively. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass, or Surgical Examination, until after the termination of the fourth year of their professional education. The fee of five guineas, paid prior to the first admission to the Primary Examination, is retained whether the candidate pass or fail to pass the examination, but is allowed as part of the whole fee of twenty-two pounds[26] payable for the diploma. A candidate, after failure at any Primary Examination, is required, on admission to any subsequent Primary Examination, to pay a further fee of three guineas, which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of twenty-two pounds for the diploma.

The fee of sixteen pounds fifteen shillings is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of eleven pounds ten shillings is returned to the candidate. A candidate, having entered his name for either the Primary or Pass Examination, who

details, such as in the application of anatomical facts to surgery, on the living person, or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents on the living person, or on the dead body; the performance, where practicable, of the operations of surgery on the dead body; the use of surgical apparatus; the examination of diseased structures, as illustrated in the contents of a museum of morbid anatomy and otherwise.

[19] The course of lectures on Chemistry included in Clause 5 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

[20] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[21] The certificate of instruction in Vaccination must be such as will qualify its holder to contract as a Public Vaccinator under the Regulations at the time in force of the Local Government Board.

[22] The winter session comprises a period of six months, and, in England, commences on the 1st of October and terminates on the 31st of March.

[23] The summer session comprises a period of three months, and, in England, commences on the 1st of May and terminates on the 31st of July.

[24] It is intended that the candidate should receive the instruction required by Clause 10 at an early period of his attendance at the hospital.

[25] Candidates can claim exemption from examination in Medicine and Midwifery under the following conditions, viz:—The production by the Candidate of a degree, diploma, or licence in medicine and midwifery entitling him to register under the Medical Act of 1858 or a degree, diploma, or licence in medicine and midwifery of a colonial or foreign university approved by the Council of the College. A declaration by the candidate, prior to his admission to the Pass Examination, that it is his intention to obtain either of the qualifications in medicine and midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said qualification, or proof of having passed the several examinations entitling him to receive the same.

[26] This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

Digitized by Google

shall fail to attend will not be allowed to present himself for examination within the period of three months from the date at which he shall have so failed to attend. A candidate referred on the Primary Examination is required, prior to his admission to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, his anatomical and physiological studies in a recognised medical school during not less than three months subsequently to the date of his reference. A candidate referred upon the Primary Examination, who shall not obtain more than half of the total minimum number of marks, is not readmitted to examination until after the lapse of six months. A candidate referred on the Pass Examination is required, unless the Court of Examiners shall otherwise determine, to produce, prior to his admission to re-examination, a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on clinical surgery, subsequently to the date of his reference.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

After the 16th October, 1884, the College will cease to grant its "Single Qualification" in Medicine, except under the following conditions:—

1st. The College will grant its Single Qualification in Medicine to Candidates who already possess a recognised British or Irish Qualification in Surgery, upon their passing an Examination (written and oral) before the Examining Board of the College, in Medicine, Clinical Medicine, Materia Medica, Midwifery, and Medical Jurisprudence. Such an Examination will be held on the first Wednesday, and succeeding days, of every month, except September and October.

2nd. Candidates who, before the 18th October, 1884, have passed the First Professional Examination of the College, will be allowed to obtain the Single Qualification under the old Regulations, provided they pass the Final Examination before the 18th October, 1886.

The Licence.—No one can obtain the licence of the College until he has completed the age of twenty-one years. Every applicant for the licence must produce evidence that he has attended the following courses at a university, or at some medical school recognised by the College:—Anatomy, six months; Practical Anatomy, six months; Chemistry, six months; Practical Chemistry, three months; Materia Medica and Pharmacy, three months; Physiology or Institutes of Medicine, three months; Practice of Medicine, six months; Clinical Medicine, six months; Principles and Practice of Surgery, six months; Clinical Surgery, three months; Midwifery, three months; Medical Jurisprudence, three months; General Pathology or Pathological Anatomy, three months; Practical Pharmacy, three months. The applicant must also produce evidence of having attended the practice of a public hospital (containing not fewer than eighty beds) during a period of not less than twenty-four months, twelve of which must have been spent in attendance on the medical wards. He must have attended for six months the practice of a public dispensary, or have acted for six months as clinical clerk or dresser in a hospital, or have been engaged for six months as visiting assistant to a registered practitioner. He must produce a certificate of having attended at least six cases of Labour under the superintendence of a qualified medical practitioner, and that he has studied Vaccination under a competent and recognised teacher.

No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be conducted partly *viva voce*, partly by written papers. Candidates for the licence of the College who have passed the first Professional Examination before a qualified body (provided it be as extensive as that required by this College) will be at once admitted to the second part of the examination in October, 1884, but not to any of the subsequent final examinations, unless they have previously obtained a recognised qualification in Surgery.

Meetings for the examination of candidates who already possess a qualification from a recognised licensing body will be held on the first Wednesday of every month (with the exception of September and October), and, if necessary, on the following days. No one is admissible to examination who has within the previous three months been rejected by any licensing board. The fee for the licence is fifteen guineas.

The Membership.—Any licentiate of a College of Physicians, or Graduate of a British or Irish University, with whose knowledge of Medical and General Science the College may be satisfied, may be admitted a Member of the College provided he shall have attained the age of twenty-four years.

Every candidate for the Membership (except in the case of medical practitioners of ten years' standing, distinguished for scientific attainments, whom the Council may see fit to exempt) shall be required to pass an examination—1. On the Principles and Practice of Medicine, including Therapeutics. 2. On one of the following subjects, to be selected by the candidate:—(*a*) Pathology, including Morbid Anatomy; (*b*) Medical Jurisprudence and Public Health; (*c*) Midwifery and the Diseases of Women; (*d*) Psychological Medicine.

The Fellowship.—No one shall be elected a Fellow of the College until he has been at least one year a member thereof, and has attained the age of twenty-five years.

The fee to be paid by a member is £31 10*s*. When a licentiate is raised to the rank of a member, he pays £21, but if his licence has been obtained subsequent to August 1st, 1876, he only pays £15 15*s*. When a member is raised to the rank of a Fellow, the fee is £31 10*s*, exclusive of stamp duty, which amounts to £25.

Qualification in Public Health.—The College now confers certificates of competency in Public Health. Fee for certificate, £18 18*s*.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

The following regulations are applicable to candidates already registered, Licentiates of one of the Colleges of Physicians of the United Kingdom, or Graduates in Medicine of a British or Irish University mentioned in Schedule (*a*) of the Medical Act, and candidates who have already entered for either of the professional examinations for the single qualification of the College.

Professional Examination.—Candidates are subjected to two Professional Examinations, conducted at separate sittings, partly in writing and partly orally.

The First Examination embraces Anatomy, Physiology, and Chemistry. Examinations will be held on Oct. 21st, 1884; Jan. 27th, April 21st, July 14th, 1885.

Candidates who desire to pass the First Professional Examination must apply to the Secretary on or before the Tuesday preceding the day of examination, and must produce certificates of attendance in regard to all those courses of study which have reference to the subjects of that examination. They must also produce evidence of having passed the Preliminary Examination. The sum of £6 6*s*. must be paid to the treasurer of the College for this examination not later than 9 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £15 15*s*. payable for the diploma.

The Second Examination embraces Surgery and Surgical Anatomy; also Medicine, Midwifery, Materia Medica, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study; in the case of candidates who began their course of study after 16th of September, 1866, it will not take place till forty-five months after the examination in general education.

Applications for examination must be made to the secretary not later than the Monday previous to the day of the examination.

Every candidate must produce to the secretary—1. Satisfactory evidence of his having attained the age of twenty-one years, and of having been duly registered. 2. The certificates of his classes. 3. The certificate of his having passed the First Professional Examination. 4. A tabular statement (for which a printed form will be furnished) exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, dispensaries, and schools attended during each session of his studies. If he have been an apprentice, he must also insert the name of his master, the date of his indenture, and the length of time for which he is bound. This statement, accurately filled up, must be attested by his signature, and afterwards delivered by the candidate to the officer of the College, to be preserved by the College. If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

The remaining fee payable to the College (being £9 9*s*.),

Digitized by Google

together with the receipt for the fee paid for the First Professional Examination, must be lodged, not later than 9 A.M. of the Tuesday preceding the examination day, in the hands of the treasurer. £5 5s. will be returned to unsuccessful candidates.

Candidates who have passed the First Examination of the College in Anatomy, Physiology, and Chemistry, and registered practitioners as defined previously, will be admissible to the Second Professional Examination on producing certificates of the whole course of study, of having passed their Preliminary and First Professional Examinations, and of having been registered. If any of the three subjects of the First Examination have been omitted, such candidates will have to undergo the First Examination on the omitted subjects; and none of the subjects set down will be omitted at the Second Examination, even if some of them should have formed part of the First Examination by another board. The fee is £15 15s. Unsuccessful candidates under this regulation receive back £11 11s.

No candidate will be admissible to examination who has been rejected by any other licensing board within the three months preceding his application to be examined.

The Dental Diploma.—Every candidate for the Dental Diploma must have attended the general lectures and courses of instruction required at a university or an established medical school recognised by the College as qualifying for the diploma in Surgery. The special courses of instruction may have been followed in a recognised dental hospital or school, or by teachers recognised by the College. The examinations will be both written and oral, and be conducted in the same manner as the ordinary surgical examinations.

Candidates for the Dental Diploma must produce evidence of having attained the age of twenty-one years, and will be required to produce a certificate of having passed the Preliminary Examination in General Education required for the ordinary licence in Surgery, or an examination equivalent to this, and recognised by the General Medical Council, except in the case of candidates who shall have commenced their professional education previous to the 1st day of August, 1878.

Candidates will also be required to produce certificates of having been engaged during four years in the acquirement of professional knowledge, and of having been during that period, or at some time previous to their examination, engaged for not less than three years in the acquirement of a practical knowledge of Mechanical Dentistry with a practitioner registered under this Act. The fee for the diploma is £10 10s.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

The Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh, have made arrangements by which, after one series of examinations, the student may obtain the diplomas of both Colleges. The general principle of this joint examination is, that it shall be conducted by a board in which each body is represented in those branches which are common to both medicine and surgery; but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery. The object of the joint examination is to give to students facilities for obtaining from two separate bodies, and at less expense, a qualification in Medicine and a qualification in Surgery. Students passing that examination successfully will be enabled to register two qualifications under the Medical Act—Licentiate of the Royal College of Physicians of Edinburgh and Licentiate of the Royal College of Surgeons of Edinburgh.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Preliminary Examinations in General Literature, in accordance with the regulations of the General Council, will be held in the Faculty Hall during the session 1884–85 on the following Fridays, commencing at 9 o'clock—namely, October 17th, 1884, March 26th, June 25th, and October 8th, 1885; and on each occasion the examination will be continued on the succeeding days. The fee for the examination and certificate is 10s.

The course of study is the same as that for the Royal College of Surgeons of Edinburgh.

The Professional Examinations are held at four periods—in January, April, July, and October. The following are the dates at which the examinations will begin in 1884–85: Oct. 20th, 1884; Jan. 13th, April 21st, July 14th, 1885.

No one is admissible to the Examination for the Single Licence of the Faculty unless he is registered as a Licentiate of one of the Colleges of Physicians of the United Kingdom or a Graduate in Medicine of a British or Irish University. Candidates who passed the Primary Examination of the Faculty before July 20th, 1884, will be admitted to the Final Examination on the rules in force before that date, provided they present themselves previous to December 31st, 1886. The Examination embraces the following subjects:—Surgery (including Operative and Clinical Surgery) and Surgical Anatomy, Clinical Medicine, Midwifery, and Medical Jurisprudence. The production of the candidate's diploma will be received as evidence that he has attended the curriculum of study required for the degree or licence which he holds; but if the curriculum of the Faculty in any subject in excess of that covered by the diploma produced, to that extent the applicant will be called upon to submit direct evidence of study. A schedule in which to tabulate the course of study attended may be had on application. This schedule should be sent to the Secretary at least one week before the day of examination.

The fee is fifteen guineas, of which the sum of seven guineas is returned to the candidate in the event of his being remitted to his studies. The fee is payable at the time of entering for examination. Candidates rejected by another board are not admissible till the expiry of six months from the date of rejection.

Certificate of Qualification in Public Health.—Candidates may be admitted to examination before they have obtained a qualification to practise; but in no case shall the certificate be granted till the candidate is registered under the Medical Act. The examinations are written, oral, and practical. The examination is divided into two parts. Part I. comprises Chemistry, Physics, and Meteorology; Part II. includes Medicine in its bearings on Sanitary Science; Sanitary Law, and Vital Statistic.

The fee is eight guineas, of which three guineas shall be payable on entering for the first part, three guineas on entering for the second part, and two guineas on obtaining the certificate.

The examination will be held on the following dates:—First part—16th April, and 23rd July, 1885. The examination for the second part will be held two days subsequent to these dates.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Examinations in the subjects of the First Professional Examination are held quarterly, in January, April, July, and October. Examinations in the subjects of the Final Examination for the licence in Medicine of the College and for the licence in Midwifery are held in the week following the first Friday in each month, except August and September. Every candidate for a licence must return his name to the Registrar of the College, and lodge with him his certificates, bank (Royal Bank of Ireland) receipt of fees, and his schedule, at least four days before the first Friday in each month.

Licence in Medicine.—Every candidate for the license of the College to practise Medicine must produce satisfactory evidence—1. Of character, from a Fellow of the College, or from two registered practitioners. 2. Of having passed an examination in general education, held by some one of the examining bodies recognised by the General Medical Council. 3. Of having been engaged during a period of four years in the study of Medicine. 4. Of having attended courses of lectures on the following subjects, at schools recognised by the College: Practical Anatomy, two courses; Physiology or Institutes of Medicine, Chemistry, Practical Chemistry, Materia Medica, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, and Midwifery—each, one course. 5. Of having attended for twenty-seven months a recognised Medico-Chirurgical Hospital, in which clinical lectures and clinical instruction in Medicine are given, the attendance not to be for more than nine months in any one year—viz., six winter, and three summer months. 6. Of having discharged the duties of Medical Clinical Clerk during six months, or of having taken notes, to the satisfaction of the physician in charge of the case, and certified under his

Digitized by Google

hand, of at least six separate Medical cases—including different varieties of acute and chronic disease—in the wards of a recognised hospital; and of having attended, during the whole period of his attendance on hospital practice, Demonstrations in the post-mortem room of a recognised hospital.—(This rule to be enforced in the case of all candidates who shall have commenced their professional studies after Sept. 30th, 1883.) 7. Of having studied Fever, for not less than three months, in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature.[27] 8. Of having attended Practical Midwifery and Diseases of Women for six months at a Lying-in Hospital or Maternity recognised by the College or, where such hospital attendance cannot have been obtained during the course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding public appointments; in either case not less than twenty labour cases must have been actually attended. 9. Of having lodged the admission fee in the Royal Bank of Ireland, Foster-place, Dublin, to the credit of the College.

The professional examination is divided into two parts: 1. Anatomy, Physiology and Practical Histology, Chemistry, and Materia Medica. 2. Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. Candidates may be examined in the subjects of the first part at the termination of the second year of study, on producing the certificates in these subjects, or in all the subjects of their education, on the completion of their medical studies. No candidate can be examined in the subjects of the first and second parts in the same month.

Candidates qualified as follows are required to undergo the second part only of the professional examination—*viz.*: (1) Graduates in Medicine of any university in the United Kingdom, or of any foreign university approved by the College; (2) Fellows, Members, or Licentiates of the Royal Colleges of Physicians of London or Edinburgh; (3) Graduates or Licentiates in Surgery; (4) Candidates who, having completed the curriculum laid down above, shall have passed the previous professional examination or examinations (where there are more than one) of any of the licensing medical authorities in the United Kingdom.

Licence in Midwifery.—Candidates for the licence in Midwifery, who are not Licentiates in Medicine, may be admitted to examination on the following qualifications: (1) The degree or license in Medicine or Surgery from any University or College of Physicians or Surgeons in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (*a*) a course of lectures on Midwifery in a school recognised by the College; (*b*) Practical Midwifery and Diseases of Women, as in Section 6 of the regulations for the Licence in Medicine.

The fees are: For the licence to practise medicine, £15 15*s*. Examination for the midwifery licence, £3 3*s*. For the licences in medicine and midwifery, if obtained within a month, to be lodged in one sum,[28] £16 16*s*. In case the candidate be a graduate, both in Arts and in Medicine of any University in Great Britain or Ireland, the fee for the licence in medicine shall be £5 5*s*. The admission fee, less the sum paid to the examiners, is returned to any candidate rejected at any of the College examinations.

The Membership.—Members of the College alone are eligible to the Fellowship. Every candidate for the membership is required to produce satisfactory evidence—1. Of having attained the age of twenty-five years. 2. Of being a licentiate of this College for three years at least; or a licentiate of one year's standing, who shall be a graduate of Arts of a university in the United Kingdom at the time of his obtaining the licence; or a licentiate of one year's standing, who shall be a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character, as testified by a fellow or member of the College, or by a fellow of the Royal Colleges of Physicians of London or of Edinburgh. 4. Of not being engaged in trade; of not dispensing medicine, or making any engagement with a chemist, or any other person, for the supply of medicines; and of not practising medicine or surgery in partnership, by deed or otherwise. 5. Of having held, during at least six months, the office of resident physician, or resident medical pupil, in a hospital recognised by the College; or of having acted for the same period as clinical clerk in the medical wards of such hospital; or of having been in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 6. Of having lodged the admission fee of twenty guineas in the Royal Bank of Ireland to the credit of the College.

Every candidate shall be required to pass an examination in (1) Principles of Medicine, including Pathology, Medical Anatomy, and Medical Chemistry. (2) Practice of Medicine, including Principles of Public Health. (3) Clinical Medicine.

The examination for the membership is held quarterly—in January, April, July, and October, and is conducted (1) by printed papers, (2) clinically, and (3) orally.

The Fellowship.—The election for fellowship takes place twice a year, on the first Friday in April, and on St. Luke's day (October 18th). Candidates must be proposed and nominated three months previously. Fee, £60.

The Certificate in Sanitary Science.—Every candidate for the Certificate in Sanitary Science must be a licentiate in medicine of the College or a registered medical practitioner of the United Kingdom. He must return his name to the Registrar of the College a week before the examination, and lodge with him a testimonial of character from a Fellow or Member of the College, or from a Fellow of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, or Dublin. Stated examinations for the Certificates in Sanitary Science are held quarterly, on the Thursday and Friday following the first Friday of the months of January, April, July, and October. The examination comprises the following subjects:—(1) Etiology and Prevention of Disease; (2) Engineering; (3) Law; (4) Chemistry; (5) Meteorology, Climatology, and Vital Statistics. The fee for the examination for licentiates in medicine of the College, and for other registered medical practitioners, is £10 10*s*., which shall be lodged in the Royal Bank of Ireland to the credit of the College before the candidate is admitted to examination.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Candidates for the Letters Testimonial of the College may present themselves either at a Stated or a Special Examination, as hereinafter set forth. Stated Examinations are held in the months of April, July, and November, commencing on dates of which due notice shall be given beforehand by the Council of the College. Candidates *cannot be admitted to these Examinations unless they be registered pupils*. They will be divided into two classes—junior and senior.

The junior class shall produce certificates of—(*a*) Having passed a Preliminary Examination recognised by the General Medical Council (into the curriculum of which the Greek language enters as a compulsory subject), and having attended the following Lectures—(*b*) three courses of lectures on Anatomy and Physiology; (*c*) three courses of lectures on Practical Anatomy, with dissections; (*d*) two courses of lectures on Chemistry; (*e*) one course of lectures on Materia Medica; (*f*) one course of lectures on Botany; and (*g*) one course of lectures on Forensic Medicine. This class shall be examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry. The fee for this examination shall be five guineas (in addition to the registration fee of five guineas).

The senior class shall produce certificates of having attended the following lectures:—(*a*) Three courses of lectures on the Theory and Practice of Surgery; (*b*) one course of lectures on the Practice of Medicine; (*c*) one course of lectures on Midwifery; also certificates of attendance on (*d*) a recognised hospital, for three winter and three summer sessions; (*e*) of instruction in Clinical Ophthalmology, three months, and of attendance for one month at the Cow-pock Institution or some other institution approved of by the Council, or under the instruction of a public vaccinator specially recognised by this College for that purpose. This class shall be examined in Surgery, Operative Surgery on the subject, and Surgical Appliances, Practice of Medicine, Medical Jurisprudence, and Prescriptions. Each of these examinations shall be partly written, partly *viva voce*, and partly practical. The fee for the senior class examination shall be fifteen guineas, returnable to the candidate in case of rejection, or to be allowed to him in case he presents

[27] Candidates who commenced their hospital studies between September, 1876, and October, 1879, will be required to conform to Rule 8, or to produce evidence of having attended for nine months a hospital which contained fever wards.

[28] Any candidate rejected at the Examination for the Licence in Medicine must pay the full amount of fee for the Licence in Midwifery.

Digitized by Google

himself a second time for the same examination. A further fee of one guinea is to be paid to the registrar.

Every candidate rejected at any of the Stated Examinations, on applying for re-examination shall be required to pay to the College, in addition to the regular fees, the sum of two guineas, to reimburse the College the necessary expense of his examination. Candidates seeking a Special Examination must make application to the Council, and, if admitted thereto, must pay five guineas, in addition to the fees for Stated Examinations. The subjects for examination, and the mode of carrying out a special examination, will be the same as those laid down for the Stated Examinations. The fees are the same as those for the Stated Examinations, as set forth above; and a rejected candidate will only be entitled to receive back fifteen guineas of the fees lodged by him.

Fellowship Examination for Candidates possessing no Qualification. — The examination shall consist of two divisions, and extend over, at least, three days; the first two of which shall be devoted to the Examination for the Letters Testimonial of the College. The third day shall be devoted to additional subjects required for the Fellowship. Candidates who do not pass the first two days' examination shall not be allowed to proceed to the third, but those who do pass shall be entitled to receive the Letters Testimonial of the College, although they may not have passed the third day's examination. No credit will be given, on a subsequent occasion, for passing a part only of either examination.

THE SOCIETY OF APOTHECARIES, LONDON.

Every candidate for a licence to practise as an Apothecary will be required to pass two examinations, the Primary and the Final. Each examination is divided into two parts, written and oral.

Examinations in Arts will be held on January 8th, 9th, 10th; April 30th; May 1st, 2nd; and on September 10th, 11th, 12th, 1885.

The course of medical study required for a licence must occupy at least four years, of which not less than three winter and two summer sessions must be passed at a recognised school or hospital. The following will be recognised and considered equivalent to eighteen months' study, in addition to the two years and a half above-mentioned:—(*a*) Attendance on the practice of a hospital or other public institution recognised by this Hall for that purpose; (*b*) instruction as the pupil or assistant of a registered practitioner, physician or surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as may be deemed satisfactory.

Course of Study.—Every candidate must attend the following lectures and medical practice: each winter session to consist of not less than six months, to commence on the 1st of October; each summer session to commence on the 1st of May.

First Year.—Winter Session: Chemistry, Anatomy, and Physiology (including Dissections and Demonstrations). Summer Session: Botany, Materia Medica, and Therapeutics, Practical Chemistry.

Second Year.—Winter Session: Anatomy and Physiology (including Dissections and Demonstrations), Principles and Practice of Medicine, Hospital Medical Practice. Summer Session: Midwifery and Diseases of Women and Children, Forensic Medicine and Toxicology, Hospital Medical Practice.

Third Year.—Winter Session: Principles and Practice of Surgery, Clinical Medical Lectures, Morbid Anatomy, Pathology, and Hospital Medical Practice. Summer Session: Practical Midwifery and Vaccination, Morbid Anatomy, Hospital Medical Practice.

Professional Examinations — The Court of Examiners meet in the Hall every Wednesday and Thursday, where candidates are required to attend at 4.30 P.M. Every candidate intending to offer himself for examination must give seven days' notice previous to the day of examination.

The Certificates required for the Primary Examination are:—Of registration as medical student. Of having passed an examination in Elementary Mechanics, recognised by the General Medical Council. Of the commencement of lectures and hospital attendance. Of the course of medical study. (The prescribed curriculum being completed to the close of the second winter session.) Of Practical Pharmacy, three months.

The Primary Examination, which may be passed after the second winter session, embraces the following subjects:—Physicians' Prescriptions and Pharmacy; Anatomy and Physiology; an examination on the Living Body; General and Practical Chemistry, conducted in the Laboratory at the Hall of the Society; Materia Medica and Botany; Histology. Rejected candidates cannot be re-examined until after the expiration of three calendar months.

The Final Examination at the termination of the medical studies embraces Principles and Practices of Medicine, including an examination of one or more patients; Pathology and Therapeutics; Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology; Microscopical Pathology. Rejected candidates cannot be re-examined until after the expiration of six calendar months.

Certificates are required of candidates for the Final Examination:—Of having completed four years' medical study, including the period spent at the hospital. Of birth. Of registration as medical student. Of the commencement of lectures and hospital attendance. (If these last two certificates have been furnished before, they need not be produced again.) Of the course of medical study. (The prescribed curriculum occupying at least forty-five months, of which not less than three winter and two summer sessions shall be passed at any recognised hospital and school of medicine.) Of having acted as clinical clerk at a recognised hospital. Of proficiency in Practical Vaccination, from a public vaccinator. Of having attended not less than twenty Midwifery cases, from any registered practitioner. Of examinations passed, if any, here or elsewhere. Of moral character. Of having been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

Fees.—The fee for the licence is £6 6*s.*; for certificate to act as assistant, £2 2*s.*

Prizes are annually offered for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most in the examination; and a silver medal and a book, or books, to the candidate who does so in the next degree. Also two prizes for proficiency in the knowledge of Botany, consisting of a gold medal to the candidate who distinguishes himself the most in the examination; and a silver medal and a book, or books, to the candidate who does so in the next degree.

Medical and Surgical Scholarship.—Each Scholarship is of the annual value of £100, and is tenable for two years on certain conditions. It is open to all students of the medical profession whose standing at the time of the examination is not less than four and not more than five years from the date of their registration, and who have obtained and possess an English medical qualification. Lectures on Botany are given at the Society's garden in Chelsea during the summer session, open to all medical students and others.

APOTHECARIES' HALL OF IRELAND.

Professional Education.—Every candidate for the licence to practise Medicine and Pharmacy must produce certificates to the following effect:—Of having passed an examination in Arts duly recognised by the General Medical Council previously to entering on professional duty. Of registration as a medical student from the Registrar of the Medical Council. Of being at least twenty-one years of age, and of good and moral character. Of pupilage to a qualified apothecary, or of having been otherwise engaged at *practical* Pharmacy under the superintendence of a registered general practitioner holding a public dispensary for a period of twelve months subsequent to having passed the examination in Arts. Of having spent four years in professional study. Of having attended the following courses, namely:—Chemistry, during one winter session; Anatomy and Physiology, during one winter session; Demonstrations and Dissections, during two winter sessions; Botany and Natural History, during one summer session; Practical Chemistry (by daily instruction in a recognised laboratory), during three months; Materia Medica during three months; Principles and Practice of Medicine during one winter session; Pathology, a course; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery, at a recognised hospital (attendance upon twenty cases); Surgery, during one winter session; Forensic Medicine, during one summer session; instruction in the Practice of Vaccination. Of having attended at a recognised hospital or hospitals the Practice of

Digitized by Google

Medicine and Clinical Lectures on Medicine, during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery, during one winter and one summer session. Of practical study, with care of patients, as apprentice, pupil, assistant, clinical clerk, or dresser. Of having performed vaccination successfully under a vaccinator recognised by the Local Government Board.

The *Examination for the Licence* is divided into two parts. The first part comprehends Chemistry, including Physics, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy; the second, Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

Candidates at the examination on Anatomy are liable to be called on to perform dissections; and at the examination on Surgery to perform operations on the dead subject.

The *Professional Examinations* will be held quarterly, and will commence on the first and second Monday in January, April, July, and October. They will be carried on as follows:—The first part on the first Monday at eleven o'clock A.M. and on the Tuesday and Wednesday succeeding at the same hour. Subjects: Chemistry, including Chemical Physics and Botany, Monday; Materia Medica and Pharmacy (the Pharmacy to include the compounding and dispensing of medicine and medical prescriptions), Tuesday; Anatomy and Physiology, Wednesday. The second part, or final examination, on the second Monday at 11 o'clock A.M.; and on the Tuesday and Wednesday succeeding at the same hour. Subjects: Medicine and Surgery, including Pathology and Therapeutics, Monday; Midwifery and Diseases of Women and Children, Tuesday; Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

Notice.—That on and after the 1st of October, 1885, candidates for the licence of the Hall will be required to produce certificates of having attended the practice of a recognised medico-chirurgical hospital or hospitals for not less than twenty-four months, including three winters and two summers.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination; for although by the last Army Warrant power is reserved to the Secretary of State for War to fill up, without an examination, a number not exceeding half the vacancies in the department, with qualified candidates recommended by the governing bodies of public schools of medicine in the United Kingdom or Colonies, this has never yet been exercised. Candidates for both services must, before being admitted to examination, possess the double qualification to practise medicine and surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian service, between twenty-two and twenty-eight, of sound bodily health, and natural born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The number of appointments to be competed for on each occasion varies according to the requirements of the services. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed his examination the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8*s.*, to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high standing in their special departments; Surgeon-General Longmore, C.B., is Professor of Military Surgery; Inspector-General Maclean, M.D., C.B., of Military Medicine; Surgeon-Major de Chaumont, M.D., F.R.S., of Military Hygiene; and Dr. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant-Professors of Medicine and Surgery, and receive practical instruction in the mode of examining recruits. The Surgeons on probation are provided with quarters, and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school. For the army this is merely a "pass," and does not affect the position gained at the entrant examination; for the Indian service the numbers obtained are added to those previously assigned, and the seniority on the list is determined by the combined results of the preliminary and final examinations. At the close of each session five prizes are awarded: the Herbert prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £20, awarded in the same manner for Military Surgery; and the Montefiore Second Prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch. The competition for the last four prizes is optional.

The conditions of admission into the Naval Medical Service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service, and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital." At present Fleet Surgeon Walter Reid, M.D., has been appointed to Haslar "for instruction of surgeons on entry," and Surgeon Gilbert Kirker, M.D., "to assist in instruction of surgeons on entry;" but we have no information as to the length of the course, the conditions under which it is conducted, or the subjects professed to be taught.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service.

Surgeon-General	2 15 0	2 0 0	Major-General

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Before being promoted they will be required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers, which may be taken at any time between the fifth and tenth year of service. It will embrace the following subjects:—(a) Surgery, operative and practical, including field surgery and transport of sick and wounded. (b) Medicine and pathology, including practical pharmacy and modes of prescribing and administering remedial measures, food, drink, &c. (c) Hygiene, within the limits treated of in "Parkes' Practical Hygiene." (d) Duties of executive medical officers during peace and war at home and abroad, and at sea, as defined in the various codes of regulations issued for their guidance. Medical officers possessing the following qualifications will be exempted from examination in medicine, surgery, and hygiene respectively, provided they have obtained their qualifications five years subsequent to their entry into the service:—(a) The Fellowship of any Royal College of Physicians or Surgeons of Great Britain or Ireland, granted under a higher standard of qualification than that for Licentiate or Member, will be accepted in lieu of an examination in medicine and surgery. (b) The diploma in Hygiene and State Medicine, or any corresponding diploma of any University in Great Britain or Ireland, such diploma being granted after examination, will be accepted in lieu of an examination in this subject. A certificate will be required from a recognised teacher of surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator. A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required. Considerable importance will be attached to the literary and scientific merits of this report.

The selection of Surgeons-Major for advancement to the grade of Brigade Surgeon is made on the grounds of ability and merit, in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential Reports. He must be physically fit for general service, and have the necessary qualifying foreign and Indian service under existing rules. He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects:—(a) Hospital organisation and administration in peace and war. (b) The administration, interior economy, command, and discipline of the Medical Staff Corps and bearer columns. (c) The relations of the medical to all other departments and corps of the army, as defined by the various Codes of Regulations in force. (d) Recruiting and invaliding. (e) The management of sick and wounded in war. (f) Field medical organisation. (g) The transport of the sick and wounded by land and sea. (h) The medical and surgical equipment and hospital arrangements for an army corps. (i) The duties and responsibilities of medical officers, quartermasters, and non-commissioned officers and men of the Medical Staff Corps in regard to the charge and supervision of stores and equipments, and the nursing, dieting, and general management of the sick. (k) The sanitary duties of medical officers in charge of camps and hospitals in the field and at the base of operations. (l) The sanitary inspection and equipment of hospital ships and troop transports, and all other sanitary duties in camps, garrisons, and quarters. (m) The origin, progress, and best methods of dealing with outbreaks of epidemic disease among troops under any given circumstance. (n) The most approved methods of securing the sick, and especially the wounded, against pyæmia, septicæmia, and all other forms of blood poisoning, and the management and treatment of such outbreaks when they occur. (o) Questions on operative surgery and practical medicine will also form part of this examination. A medico-topographical report will be required of any district or country in which British troops have been, or are likely to be, actively employed, as well as a sketch of the medical arrangements suitable for an army corps operating in such a district or country, compiled by the officer, and certified to be his own composition and in his own handwriting.

Brigade Surgeons, to be eligible for selection as Deputy-Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy-Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

Inspector-General	2 15 0	1 13		

Surgeons are promoted to Staff Surgeons after twelve years' service, provided they pass the requisite examination, and Staff Surgeons to Fleet Surgeons after twenty years, if recommended by the Director-General. Deputy Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed or five years' home service. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and the grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay, time on half-pay will be taken as equivalent to one-third service on full-pay.

METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 750 beds, of which 676 are in the hospital at Smithfield, and 75 are for convalescent patients at Swanley.

Four house-physicians, ten house-surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward-dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward-dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Open Scholarships in Science of the value of £130 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, Physiology (not more than four subjects to be taken), and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The Examination is confined to students of the Hospital of less than six months' standing, and will be held in October. The Jeaffreson Exhibition, of the value of £50, and tenable for two years, is awarded after examination in the subjects of General Education. It is now an Open Exhibition. A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry. Lawrence Scholarship, and Gold Medal, of the value of forty guineas (founded in 1873 by the family of the late Sir Wm. Lawrence. Two Brackenbury Scholarships in Medicine and Surgery, £30 each. Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, £99 15*s.*, payable by instalments, including the fee of £2 2*s.* for matriculation, which involves no examination. Matriculated students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the scholarships, gold medal, and Pereira prize.

Two entrance scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*. English, Latin, French, or German, Mathematics; *Optional* (only one of which may be selected), Chemistry, Mechanics, German or French; the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete on or before Saturday, September 20th, 1884. Two scholarships are open for competition among the matriculated students: the Llewellyn Scholarship of £25, for students who have just completed their second year; and the Golding Scholarship of £15, for students who have just completed their first year. The Pereira prize of £5 is open to all matriculated students, and is awarded annually for the best clinical reports. The Governors' Gold Medal is given for excellence in clinical work. Silver or Bronze Medals are awarded to the most distinguished students in all classes.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointments of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, registrar's assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. A reduction is made in the case of students who have already completed a part of their course at an English university. The house-physician and house-surgeon receive their board and lodging free, and *no payment* is made for the appointment. Gentlemen are admitted to the hospital practice and lectures required by the College of Physicians and Surgeons and the Society of the Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £15 for each subsequent year of attendance. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previous to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession, and for moral conduct, open to perpetual pupils in their fourth year of study. Sir Charles Clarke's Prize (interest of £200 Consols) for good conduct. The Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; the Brodie Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy, and General Proficiency Prizes, value £10 10*s.* each, for students of each year.

GUY'S HOSPITAL.—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students, according to merit, and without payment. The house-physicians, of whom there are three constantly on duty, one as junior and two as seniors, hold office for six months each, the first two months in the former capacity, the other four in the latter. The duty of the junior house-physician is to attend in the medical out-patient room three times a week, in a room adjoining that occupied by the assistant-physician for the day, and prescribe for those patients who are not seen by the assistant-physician. The senior house-physicians are chiefly occupied in the medical wards, and attend to all emergencies that may arise in the absence of the physicians. They have separate rooms in the clinical building, and are boarded at the charge of the hospital. The house-surgeons, of whom there are also three on duty, hold office for six months each. During the first two months the house-surgeon assists in the out-patient department. During the next two months he has the general superintendence of the surgical casualty department, and assists the senior when required; and subsequently, as senior house-surgeon, he has, in the absence of the surgeons and assistant-surgeons, the care of the patients in the surgical wards, and lives during these four months in the hospital, being boarded free of expense. The dressers are selected from those gentlemen who have completed their third winter session, and who have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons free of expense. Two obstetric residents reside and are boarded in the hospital.

Scholarships, Prizes, &c.—Open scholarships of the value of £131 5*s.* in Arts, Latin, Greek, Mathematics, and modern languages. Open Scholarship of £131 5*s.* in Science. Subjects: Inorganic Chemistry, Zoology, Botany, Physics (these will be competed for on Thursday, September 25th). At the end of the summer session: first prize £50; second prize, £25. Subjects: Anatomy, Physiology, Chemistry, Materia Medica, and Botany, or Comparative Anatomy.—For Students in their second year: First prize, £25; second prize £10. Subjects: Anatomy, Physiology. The Sands Cox Scholarship of £15 per annum for three years. Sub-

Digitized by Google

ject: Physiology. The Michael Harris Prize of £10 for Anatomy. For students in their third year: First prize, £25; second prize, £10. Subjects: Medical and Surgical Anatomy, Midwifery, and Therapeutics. Fourth year's students: First prize, £25; second prize, £10. Subjects: Medicine, Surgery, Midwifery, and Medical Jurisprudence. For senior students: The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; the Gurney Hoare Prize of £25 for Clinical Medicine and Surgery; the Beaney Scholarship of 30 guineas for Pathology; the Mackenzie Bacon Prize of 10 guineas for Ophthalmoscopy; the Mackenzie Bacon Prize of £15 for Nervous Diseases; the Burdett Prize, value £10, for Hygiene. The Physical Society awards the following prizes: Two of £5 each to the members who send in the best essays on selected subjects; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the sessions.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the clinical clerks, and the house-surgeon and dressers, are selected by examination from among those matriculated students of the College who are pupils of the hospital. Rooms are provided within the walls of the college for the residence of a limited number of matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science and Literature. College Scholarship: One of £40 per annum for two years; one of £30, for one year; three of £20, for one year. The Daniell Scholarship, for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4*s*. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital is under the direction of a College board, composed of six members of the hospital staff, and six of the house committee. The executive authority is committed to a Warden. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 7388, out-patients 62,256.

The following Scholarships and prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 22nd, 23rd, and 24th, 1884. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered; and are not eligible to compete for the Buxton Scholarships:—The two Buxton Scholarships, value £30 and £20, will be offered for competition on September 25th, 26th, and 27th, 1884. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session by first and second year students. The Letheby Prize, value £30, for proficiency in Chemistry. (At the end of the summer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance. A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Surgery. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.) The Duckworth Nelson Prize, value £10, will be offered biennially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery. The Hutchinson Prize, value £35, will be given triennially to the author of the best essay upon a subject in Clinical Surgery. Candidates must be full students of the hospital who have not been registered more than ten years. Out-patients Dressers' Prizes. Six prizes, of the aggregate value of £60, will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons. Two Dissection Prizes, value £6 and £4.

ST. MARY'S HOSPITAL.—There are five resident medical officers, four of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee.

Two demonstrators of anatomy are appointed annually with a salary of £70 and £50 respectively; a demonstrator of physiology at £100 a year, and a medical tutor at £100 a year. All these officers are eligible for re-election.

A Demonstratorship in Pathological Anatomy, of the value of £15, and tenable for six months, will be given by competitive examination in Pathology and Morbid Anatomy, among those students who have completed their third winter session. The holder of the scholarship will assist the pathologist in the discharge of his duties in the Museum and Dead-house.

Two Prosectors of Anatomy, and two Assistant Demonstrators of Physiology, are appointed annually, and receive a certificate and £5 each for satisfactory service in their respective departments.

All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients.

A Maternity Department is attached to the hospital. There are special departments for Diseases of the Eye, the Ear, the Skin, and the Throat, in which clinical demonstrations are constantly given by the physicians and surgeons.

Scholarships, Prizes, &c.—Five Open Scholarships in Natural Science, one of the value of £100, and four of £50 each, will be offered for competition on Tuesday, September 23rd, and following days.

In addition to the open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £25, and £30, for the first, second, and third years respectively.

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. The Museum has recently been rearranged and a complete catalogue prepared of the various specimens. Two Entrance Scholarships, of the annual value of £25 and £20, and tenable for two years, also an Entrance Science Scholarship, value £50, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10*s*., is awarded to students at the end of their first year. The Lyell Medal is awarded annually for proficiency in Surgical Anatomy and Practical Surgery. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1886. The Governors' Prize of twenty guineas is also awarded annually to the student who shall most distinguish himself during his three years' curriculum. Valuable class prizes are also given, and ten resident clinical appointments are annually awarded, after

Digitized by Google

competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense. The tutors assist all general students, especially those who are preparing for examination, free of charge; and their instruction is arranged with a view to avoid the necessity of students obtaining any private tuition apart from that of the Medical School. The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and by the Society of Apothecaries is 90 guineas, if paid in one sum on entrance. The fees may be paid by instalments—£40, first year; £40, second year; £20, third year; £5, fourth year.

The clinical clerk and dresser of the physician and surgeon of the week dine at the board-room table, free of charge. A limited number of general students are also allowed to dine at the board-room table. The paid offices of medical registrar, surgical registrar, resident medical officer, and demonstrator of anatomy are open to qualified men as they become vacant.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year* 1884-85.—For First-year's students: Two Entrance Scholarships in Natural Science of the value of £100 and £60 respectively, open to all first-year's students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer £15 and £10. For Second-year's Students: The Peacock Scholarship of 40 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes, £42, £20, and £10, and the Prosector's Prize of £5; summer, £15 and £10; with the dresserships and the clinical clerkships. For Third-year's students (winter): Second Tenure of Scholarship £42, and prizes of £20, £15, and £10; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £20, awarded biennially to students who shall be from three to six years' standing, for the best Physiological Essay, to be illustrated by preparations and dissections; the next award will be made in 1886. The Cheselden Medal for Surgery and Surgical Anatomy; and the Mead Medal, for Practical Medicine, are awarded annually to fourth-year's students. The Solly Medal, with a prize from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical Cases. The next award will be made in 1886. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year's student. The house-physicians, house-surgeons, assistant house-physician and surgeon, and resident accoucheur are chosen from gentlemen who have obtained their professional diplomas according to merit, and, with the dressers, are provided with rooms and commons. Two hospital registrars, at £100 per annum each, will be selected from gentlemen distinguished for merit.

The medical and surgical casualty out-patients are seen by the resident assistant-physician, the resident assistant-surgeon, the house-physicians, house-surgeons, and dressers, at from 12 to 1 o'clock daily.

UNIVERSITY COLLEGE, LONDON.—The fees for lectures and hospital practice required by the College of Physicians and Surgeons and the Society of Apothecaries during the student's entire course amount to 125 guineas if paid in one sum, or 130 guineas if paid by instalments—viz., first year 60 guineas, second year 50 guineas, third year 20 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The next examination will take place at the College on September 25th and 26th. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Fellitter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Erichsen Prize, a surgeon's operating case of the value of £10 10*s.*, awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class. The appointments of demonstrators of anatomy, of resident medical officer to the hospital, and of surgical registrar—all of which have emoluments attached to them—are almost invariably conferred upon students of the College. Physicians' assistants, house-surgeons, midwifery assistants, physicians' clerks, surgeons' dressers, ward clerks, and ophthalmic surgeons' assistants are selected from the pupils, without additional fees.

WESTMINSTER HOSPITAL.—The Hospital contains upwards of 200 beds. There are separate departments for Disease of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

A Curator of the Museum and Pathologist, with a salary of fifty guineas, and a Medical and a Surgical Registrar are appointed annually, each with a salary of £40. Two House-Physicians, a House-Surgeon, and a Resident Obstetric Assistant are appointed for six months after examination, and are provided with rooms and commons. The Senior House Physician, who is also the chloroformist to the hospital, receives in addition an honorarium of twenty guineas. An Assistant House-Surgeon is appointed from among the senior students; he is provided with commons at the hospital table. Clinical Assistants to the Physicians and Surgeons, and to the officers in charge of special departments, are appointed from students of the fourth year.

Scholarships and Prizes.—The Fence and Houldsworth Entrance Scholarship, on alternate years, each £40 a year; and one Entrance Scholarship value £40. The Treasurers' Prize, an exhibition in Anatomy, Physiology, and Chemistry, value £10 10*s.*, tenable for one year for first year's men. A Prize of £2 2*s.*, by Mr. James Black, to the first year's student who is most regular and diligent in the Dissecting Room. The President's Prize, a Scholarship in Anatomy, Histology and Physiology, value £21, given by His Grace the Duke of Westminster, President of the Hospital, to student of second year (to be styled Assistant Demonstrator). At the end of the third summer, Prizes of £5 each (books or instruments), in Clinical Medicine and Clinical Surgery. Frederick Bird, Medal and Prize, value £15, to students who have completed their fourth winter; subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road.—Consulting Surgeon: Frederick Le Gros Clerk. Physicians: Drs. Cholmeley, Cook, Robert Bridges, Burnet, and Beale. Obstetric Physicians: Drs. Gustavus C. P. Murray and Faucourt Barnes. Ophthalmic Surgery: Mr. R. Marcus Gunn. Surgeons: Messrs. Gay, W. Adams, W. Spencer, Watson, J. Macready, and C. B. Lockwood. Aural Surgeon: Mr. A. E. Cumberbatch. Chloroformist: Mr. George Eastes. Dental Surgeon: Mr. E. Keen. House-Surgeon: Mr. Francis A. Stokes. Junior Resident Medical Officer: Mr. H. M. Sutton. Dispenser: Mr. B. Marks.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Consulting Physicians: Dr. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S., Dr. J. E. Pollock. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. E. Thompson, and F. Roberts. Assistant-Physicians: Drs. T. H. Green, J. M. Bruce, J. Fowler, P. Kidd, C. Y. Biss, and C. T. Acland. Pathologist: Dr. P. Kidd. Dental Surgeon: Mr. C. J. Noble.

Digitized by Google

Resident Medical Officer: Dr. H. D. Waugh. Secretary: Mr. H. Dobbin.—Three Clinical Assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms £3 3s. for three months; perpetual, £5 5s. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and Indian Medical Boards. The hospital contains 192 beds. 137 additional in the new extension building.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Established 1814. 26 beds. Consulting Physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. P. J. Hensley, Gilbart-Smith, and D. W. Finlay. Assistant-Physicians: Drs. W. Murrell, W. H. White, and J. J. Pringle. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. Pearce Gould. House-Physician: Mr. Halpin. In-patients, 576; out-patient cases, 7432. This hospital has recently been enlarged by the addition of a very complete new out-patients' department, and wards for 14 additional in-patients; and is now being still further enlarged by the addition of wards for about 60 more in-patients. The office of house-physician, tenable for six months, and for which a sum at the rate of £80 per annum is voted in lieu of board, is filled up in April and October.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—The new hospital, now in course of building, will contain £180 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2 30 P.M. In- and out-patients' practice and electrical room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physicians for out-patients: Drs. H. Charlton Bastian, W. R. Gowers, and Ferrier. Assistant-Physicians: Drs. Ormerod and Beevor. Surgeon: W. Adams, F.R.C.S. Resident Medical Officer and Registrar: J. Oliver.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. The hospital, founded in 1804, and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by 1988 persons. The out-patients are yearly over 20,000; attendances, 121,190. Operations are performed daily from half-past ten to one o'clock, and three surgeons attend on each day: Mr. Streatfeild, Mr. Waren Tay, and Mr. Adams, on Monday and Thursday; Mr. Lawson, Mr. Couper, and Mr. Tweedy, on Tuesday and Friday; Mr. Hulke, Mr. Nettleship, and Mr. Gunn, on Wednesday and Saturday. Students are admitted to the practice. Fees for six months, £3 3s.; perpetual, £5 5s.; with admission to demonstrations and lectures, to be given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants. The Secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, 19, King William-street, West Strand.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at two o'clock. The following are the days of attendance of the surgeons: Mr. Power, Monday and Friday; Mr. Rouse, Tuesday and Saturday; Mr. Macnamara, Monday and Thursday; Mr. Cowell, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special Demonstrations and Lectures will be given during the session. Secretary, Mr. T. Beattie-Campbell.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. House-Surgeon: Mr. H. F. Baker. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: Six months, £3 3s.; twelve month, £5 5s.; perpetual, £10 10s.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry, by Dr. J. Walker, on Wednesdays at 5 P.M. In summer, by Mr. Coleman, on Dental Surgery and Pathology, on Tuesdays and Fridays at 8 A.M., and by Mr. Arthur Underwood, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. *Fees:* General fee for special lectures required by the curriculum, £15 15s.; fee for two years' hospital practice required by the curriculum, £15 15s.; total fees for lectures and practice, £31 10s. Hospital Surgeons: Messrs. Hepburn, Woodhouse, Gregson, Hutchinson, Moon, and Canton. Assistant-Surgeons: Messrs. Read, Underwood, Claude Rogers, Parkinson, Storer Bennett, and Truman. Chloroformists: Messrs. Braine, Bailey, Bird, and Mills. House-Surgeon: Mr. Buckland. Assistant House-Surgeon; Mr. King. Medical Tutor: Mr. W. Paterson. The winter session will commence October 1st. All communications to be addressed to Mr. Morton Smale, Dean.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich, S.E. This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. There is a House-Physician and a House-Surgeon. Honorary Consulting Physicians: Dr. Robert Barnes, F.R.C.P., and Dr. Richard Quain, F.R.C.P. Visiting Physicians: Drs. John Curnow, F.R.C.P., and R. E. Carrington, M.R.C.P. Honorary Consulting Surgeon: Mr. George Busk, F.R.C.S., F.R.S., &c. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Medical Officer, Well-street Dispensary: Mr. E. Muirhead Little, M.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. Secretary: Mr. W. Thomas Evans.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Sturges, Gee, and W. B. Cheadle. Assistant-Physicians: Drs. R. J. Lee, Thomas Barlow, D. B. Lees, Montagu Lubbock, and Abercrombie. Surgeons:—Mr. Howard Marsh, Mr. Edmund Owen, Mr. J. H. Morgan, Mr. Bernard Pitts, and Mr. Arbuthnot Lane. Ophthalmic Surgeon: Mr. R. Marcus Gunn. Surgeon-Dentist: Mr. A. Cartwright. Secretary: S. Whitford. There are now 121 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total 173. In-patients last year, 943; out-patients, 14,700. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, W.—Physicians to the in-patients: Drs. Hope and Chapman Grigg. This hospital has been recently enlarged and is in full operation. It receives nearly 700 patients annually, besides having a large out-patient maternity. The pupils are permitted to see the practice in both departments. Medical pupils are received at all times of the year. Pupils enjoy unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases that present themselves in both departments. Certificates of attendance at this hospital are received by all universities, colleges, and licensing bodies; and a diploma is granted in midwifery. Monthly nurses and midwives are received for training.

For further particulars, application should be made to the Secretary, at the hospital.

THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road.—Instituted 1816. Consulting Physicians: Dr. Wilks, Dr. John Williams. Consulting Surgeons: Mr. J. Cooper Forster, Mr. Edwin Canton. Physicians: Drs. W. A. Duncan, W. B. Haddon, W. Park, and G. Gulliver. Surgeon: Mr. H. C. Jacobson. Assistant-Surgeon: Mr. E. Overman Day. Surgeon Dentist: Mr. W. Whitehouse. Resident Medical Officer: Dr. Sunderland. Secretary: Mr. R. G. Kestin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

HOSPITAL FOR WOMEN, Soho-square, W.—Physicians: Drs. Protheroe Smith, Heywood Smith, C. H. Carter, Richard T. Smith. Assistant-Physicians: Dr. E. Holland, Mr. J. A. Mansell Moullin, Dr. Bedford Fenwick, Dr. James Oliver. Surgeon: Mr. H. A. Reeves. Assistant-Surgeon: Mr. S. Osborn. Registrar: Dr. Bedford Fenwick. Anæsthetist: Dr. Dudley Buxton. Pathologist: Dr. James Oliver.

Clinical Department.—Qualified medical men, students of three years' standing, are appointed for terms of three months, to act as assistants to the Physicians and Surgeons of the in- and out-patients' departments. Thorough practical

Digitized by Google

instruction in Gynæcology can be thus obtained. The in-patients in 1883 numbered 573, the out-patients 4980. Two valuable prizes are offered annually for competition. Clinical lectures are given on alternate Thursday afternoons throughout the winter session. Fee for a three months' course three guineas. Any further information can be obtained by letter addressed to the Registrar at the Hospital.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The Hospital contains 60 beds and 12 at the home at Margate; and has a large out-patient department (over 500 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physicians to the out-patients: Drs. Albert Venn, T. Colcott Fox, F. D. Drewitt, and Henry Philpot. Surgeon: Mr. Cowell. Surgeons to the out-patients: Messrs Churchill and Walter Pye. Dental Surgeon: Mr. Francis Fox. House-Surgeon: Henry Blatherwick. Registrar: John A. Shaw. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under:—Medical cases: Daily, except Saturday and Sunday, at 9 A.M.; also on Mondays and Thursdays at 1.30. Surgical cases: Daily, except Monday and Thursday, at 10 A.M. Dental cases: Saturdays at 9 A.M.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Consulting Physicians: Dr. Robert Barnes and Sir Andrew Clark, Bart., M.D. Consulting Surgeon: Mr. Buxton Shillitoe. Consulting Ophthalmic Surgeon: Mr. George Cowell. Physicians: Dr. Eustace Smith, and Mr. Horatio B. Donkin. Surgeons: Mr. Arthur Cæsar and Mr. H. A. Reeves. Assistant Physicians: Mr. R. W. Parker, Dr. H. Radcliffe Crocker, and Dr. G. N. Pitt. Administrator of Anæsthetics: Mr. Thomas Bird. Medical Officer: Mr. J. Scott Battams. Secretary: Mr. Ashton Warner. The hospital contains 92 beds, besides 10 beds in an infirmary for nurses and children who require isolation.

WEST LONDON HOSPITAL, Hammersmith-road, W.—By a recent enlargement this hospital has now 100 beds. In 1882 (47 beds), 678 in patients and 13,503 out-patients were treated. There are two appointments of House-Surgeon, each tenable for six months, salary £80 per annum, no board. A new one of Registrar, honorarium, £25 per annum. Also appointments for a limited number of clinical Assistants. Physicians: Drs. G. Goddard Rogers, J. C. Thorowgood, D. W. C. Hood. Physician for Diseases of Women: Dr. Alfred Wiltshire. Surgeons: Messrs. Bruce Clarke, C. B. Keetley, and F. Swinford Edwards. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Secretary: Mr. R. J. Gilbert.

A Preparatory School of Medicine has recently been opened in connexion with this hospital and a definite Course of Practical Instruction is now offered to students who wish to prepare themselves for either one of the medical schools of the metropolis. The objects now aimed at are: 1. To give in a more complete and systematic manner than has heretofore ever been attempted all the advantages of a year's pupilage at a first-class provincial infirmary or county hospital. 2. To give instruction in Natural Science. 3. To give commencing medical students an early insight into medical work, so that they may, without needless loss of time or money, be able to judge whether or not they have chosen the right profession. Instruction will be given in the following subjects:—Elementary Medicine, Elementary Surgery, Elementary Physiology and Histology, Materia Medica and Pharmacy, Osteology, Physics, Chemistry, and Botany.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeons: Mr. Prescott Hewett and Mr. W. Morrant Baker. Physicians: Drs. Fred. Willcocks, F. Taylor, N. I. C. Tirard, James Goodhart. Surgeons: Messrs. H. G. Howse, R. Clement Lucas, and C. J. Symonds. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. Newland Pedley. House-Surgeon: Dr. W. H. C. Newnham. Hon. Secretary: Dr. I. Dobree Chepmell.

THE ALL SAINTS CHILDREN'S HOSPITAL, Margaret-street, W.—Twelve beds; chiefly for Chronic Joint Diseases. Founded by the All Saints Sisterhood. Surgeon: Mr. Noble Smith.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, AND SURGERY.—This school is intended to meet the requirements of two distinct classes of students—i.e., (1) Advanced students and qualified practitioners, who may wish either to extend their knowledge of the foregoing subjects or to recall to mind what they once knew and have since forgotten; (2) beginners entering upon their medical studies by a short term of apprenticeship. For the former, rapid advance classes, complete in three months, but still thoroughly practical, are provided; and for the latter, when required, more elementary classes of six months' duration. The dissecting-room is open daily. The Physiological Laboratory is fitted up with the requisites for practical work, and every effort is made to render the teaching thoroughly practical and demonstrative. The operations of surgery are all performed on the dead body by the students. Private address: 16, Woburn-place, Russell-square.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures on Chemistry and Pharmacy by Professor Redwood, Ph.D., F.I.C., F.C.S., and Mr. W. R. Dunstan, F.C.S. Botany and Materia Medica by Professor Bentley, M.R.C.S. Eng., F.L.S. Practical Chemistry, Professor John Attfield, Ph.D., F.R.S., F.I.C., F.C.S., Director of the Laboratories; F. W. Short, Demonstrator; E. J. Eastes, Assistant-Demonstrator. The session commences on Wednesday, October 1st, at 9 A.M. Application for admission to the School, or for further information, may be made to the professors or their assistants in the lecture theatre or laboratories, 17, Bloomsbury-square, London, W.C.

ENGLISH PROVINCIAL HOSIPTALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—120 beds. Honorary Consulting Physician: Dr. Coates. Physicians: Drs. Goodridge, Cole, and Fox. Surgeons: Messrs. Stockwell, Fowler, and Freeman. Assistant-Surgeons: Messrs. Green, Scott, and Ransford. Honorary Medical Officers for Out-patients: Dr. Field, and Messrs. Cowan and Craddock. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford Hopkins. The hospital is recognised by the General Medical Council, and licensed for dissection. It has a good library and an excellent museum, containing a large number of interesting specimens, both in Pathology and Comparative Anatomy. A year spent at the hospital counts as one out of the four required before qualifying for practice. Fees for attending the hospital practice, six months, £5 5*s.*; twelve months, £10 10*s.* Instruction in Practical Pharmacy, £5 5*s.* The number of patients admitted during the past year was 1053; out-patients 8914.

For further particulars apply to the Registrar and Curator.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. The examination for this prize in 1885 will be held in the last week in March. Two Ingleby Scholarships will be offered annually after examination in Obstetric Medicine and Surgery, and Diseases of Women and Children. The Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of thirty guineas each. The orphan sons of former students of the Birmingham Medical School shall have priority of election. No Sydenham scholars shall be elected whose age exceeds twenty-three years on the day of election. The Scholarships shall be held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually of the value of thirty guineas. They are held for three years, one third being paid each year, subject to good behaviour. Students of Queen's College are qualified to compete for all Scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

THE GENERAL AND THE QUEEN'S HOSPITALS, BIRMINGHAM.—*The General Hospital.*—Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Russell, Wade, Foster, and Rickards. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Saundby and Simon. Assistant-Surgeons: Messrs. Archer and Haslam.—*The Queen's Hospital:* Consulting Obstetric Surgeon: Mr. Berry. Consulting Surgeon: Mr. S. Gamgee. Physicians: Drs. Sawyer, Carter, and Hunt. Surgeons: Messrs. Furneaux Jordan, Wilders, Bennett May, and Lloyd. Obstetric Surgeon: Mr. John Clay. Ophthal-

mic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Physician for Out-patients: Dr. Suckling. Casualty Surgeons: Messrs. Hawkins and Moore.

MASON SCIENCE COLLEGE, BIRMINGHAM.—Founded 1875. Opened 1880. The session will commence on October 3rd. Instruction is given in Science and Arts, and students are prepared for the various examinations of the University of London. Full particulars may be obtained on application to the secretary.

BRISTOL SCHOOL OF MEDICINE (affiliated to University College, Bristol).—Students can complete in Bristol the entire course of study required for the Medical and Surgical Degrees of the University of London, and for the Diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given at University College, Bristol, are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; while the Medical School, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above Examining Boards. All necessary information may be obtained from the Dean of the Bristol Medical School. Further particulars regarding the Infirmary may be obtained from the Dean of the Infirmary Faculty, Dr. Spencer, and respecting the Hospital from the Dean of the Hospital Faculty, Dr. Markham Skerritt.

BRISTOL GENERAL HOSPITAL.—164 beds. Physicians; Drs. Markham Skerritt, Harrison, and Baron. Physician Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, Keall, and Pickering. Dentist: Mr. Parson. House-Surgeon: Mr. Penny. Physician's-Assistant: Mr. Rudge. Assistant House-Surgeon: Mr. Cornish. Clinical clerkship, six months, five guineas. Dresserships, six months, five guineas. Obstetric clerkship, three months, three guineas. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women, and in Dental Surgery.

Further information may be obtained of the Secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Faculty.

BRISTOL ROYAL INFIRMARY.—250 beds. Physicians: Drs. Spencer, Shingleton Smith, Waldo, and Shaw. Surgeons: Messrs. Board, Dowson, Prichard, Cross, and Greig Smith.

Pupils are entitled to attend the practice not only of their own physician or surgeon, but also that of all the physicians or surgeons. Surgical pupils, on requiring the requisite experience, are permitted to dress all the out-patients, and also to reside in the house in weekly rotation, where they are in charge of all the casualties under the supervision of the house-surgeon. A Pathological Clerk, who performs all the post-mortem examinations, is appointed for three months from among the senior students. Physician for the out-patients, Dr. Prowse; House-Physician, Dr. Fenton Evans; House-Surgeon, Mr. J. Paul Bush; Assistant Resident Officer and Pathologist, Mr. John Dacre. In-patients, last year, 3184; out-patients, 25,696; total, 28,880.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Clinical Lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery, in the wards and out-patient rooms, is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical clerks and dressers are selected from students according to merit, and without payment.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—*Scholarships, &c.*—Four University of Durham Scholarships, of the value of £100 each, awarded one every year, for proficiency in Arts to full students in their first year only. The Dickinson Scholarship, value £15 annually, with a gold medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20 annually, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value £35 annually, for Medicine. The Gibb Scholarship, value £25 annually, for Pathology. The Goyder Memorial Scholarship, value about £15, awarded for Clinical Medicine and Clinical Surgery in the Infirmary. At the end of each session a Silver Medal and Certificates of Honour are awarded in each of the regular classes. An Assistant Curator of the Museum is annually appointed from among the senior students, and receives £12 as an honorarium. Four Assistant Demonstrators of Anatomy (each receiving an honorarium of £5), Assistant Physiologists, Pathological Assistants, and Assistants to the Dental Surgeon are also elected. Four times in the year, two Resident Medical Assistants, two Resident Surgical Assistants, three Non-resident Clinical Clerks, and sixteen Non-resident Dressers (eight for the In-patient and eight for the Out-patient Department), are appointed for three months. The Medical and Surgical Assistants are provided with apartments and board in the Infirmary, on payment of five guineas for three months.

GENERAL KENT AND CANTERBURY HOSPITAL.—Open for the reception of patients April 26th, 1793. 47,300 in-patients and 83,643 out-patients have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society, for £7 7*s*. Operation day, Thursday, 11 A.M. Consulting Physician: Dr. Alfred Lochee. Physician: Dr. Henry Alex. Gogarthy. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles, Holttum, Frank Wacher, T. Whitehead Reid, and John Greasley. Dentist: Mr. Martin L. Ball. House-Surgeon: Mr. F. E. Hubbard. Assistant House-Surgeon and Dispenser: Mr. A. J. Griffith. Secretary: Mr. Charles H. Read. Over one thousand dental cases are attended in a year.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 320 in-patients, surgical and medical, and during the last year 3754 in-patients and 20,971 out-patients were treated; these numbers show a remarkable increase, if compared with statistics of ten years ago, when only 11,500 out-patients were seen. An idea of the extent of operative work may be gleaned from the fact of 612 major operations and 439 ophthalmic operations having been performed in 1883; during the same period ether was administered 2000 times. In consequence of the increase of work, two honorary Assistant-Surgeons were appointed last year, and two honorary Assistant-Physicians this year, to take charge of and to teach in the out-patient department. Clinical teaching is done daily in the wards, and Clinical Lectures are given in the operating-room. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. The Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students.

The Leeds Medical School has undergone a complete revolution this year by its incorporation with the Yorkshire College, which is expected to become affiliated with the Victoria University almost immediately, when its students will be able to obtain a university degree in their ordinary curriculum. The subject of Physiology will in future be taught by a Professor, who will devote the whole of his time to the work of his Chair, as will also be the case with a paid Demonstrator of Anatomy, who will be assisted by Honorary Demonstrators. All the other courses required by examining boards are given by Professors and Lecturers. The Museums and Library offer special advantages. Several valuable prizes are given at the end of each session. A House-Physician and a House-Surgeon are elected from time to time; there are also five resident assistant medical officers, who continue in office one year, and are chosen from the senior students of the school.

UNIVERSITY COLLEGE, LIVERPOOL.—Three house-surgeons and two house-physicians are elected every six months from the pupils of the school who have obtained a qualification. Nine clinical dressers and nine clerks are elected quarterly, and post-mortem clerks for six weeks. Pupils of the infirmary are admitted to learn pharmacy in the dispensing department for six months. Three Scholarships of £21, held for two years, and one of £16. The hospital contains 300 beds, including 40 beds for the treat-

Digitized by Google

ment of diseases of women. The Lock Hospital adjoining contains 60 beds.

LIVERPOOL NORTHERN HOSPITAL.—142 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Paul. Senior House-Surgeon: Mr. A. H. Gordon. Junior House-Surgeons: Mr. F. Knight and Mr. J. R. L. Dixon. 200 beds. Clinical Lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships open to all students. Special wards for accidents and diseases of children.

NORFOLK AND NORWICH HOSPITAL.—150 beds. One year's attendance recognised by examining boards. Fees: For the physicians' practice, five guineas for six months; ten guineas, perpetual. For the surgeons' practice, including dresserships, £10 for three months; £15 for six months; £20 for one year; £30 for two years; and £40 perpetual. Pupils resident and non-resident. Physicians: Dr. Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. D. D. Day.

NORTHAMPTON GENERAL INFIRMARY.—Established 1743; rebuilt 1793. In-patients, 1693; out-patients, 8223. Beds, 144. Physicians: Dr. Buszard and Dr. Jones. Surgeons: Messrs. Kirby Smith and G. H. Percival. House-Surgeon: Mr. J. Oswald Lane. Assistant House-Surgeon: Mr. W. A. Winwood Smith. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Physiology, Pathology, and Materia Medica, a great extension of the school buildings has been made. This addition is now completed, and will be opened for regular work at the beginning of the winter session. The departments of Anatomy, Physiology, Chemistry, and Zoology are taught by professors who devote the whole of their time to the duties of their respective chairs. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the medical school and infirmary. The following scholarships and prizes are open to students of the medical school:—1. A Dauntesey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose age does not then exceed twenty-five years. The subjects of examination are—(*a*) General and Comparative Anatomy; (*b*) Physiological Botany; (*c*) Chemistry; (*d*) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. 4. Two Platt Exhibitions of the value of £15 each, to be competed for by first and second year's students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY.—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, Henry Browne, Wm. Roberts. Consulting Surgeons: Mr. George Bowring and Mr. Lund. Physicians: Drs. Henry Simpson, John E. Morgan, D. J. Leech, J. Dreschfeld. Assistant-Physicians: Drs. James Ross and Graham Steell. Obstetric Physician: Dr. John Thorburn. Surgeons: Messrs. F. A. Heath, Walter Whitehead, Thomas Jones, James Hardie. Assistant-Surgeons: Messrs. Fred. A. Southam and G. A. Wright. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. David Grant. Resident Surgical Officer: Mr. Bilton Pollard. Medical and Surgical Registrar: Mr. A. H. Young. Pathological Registrar: Dr. Robert Maguire. Assistant Medical Officers: Drs. S. Moritz and A. T. Wilkinson. General Superintendent and Secretary, Mr. W. L. Saunder.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including twenty-eight for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Special classes are held for clinical instruction on Saturday afternoons during the winter months. Out-patients are seen daily at 9 A.M. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright.

SHEFFIELD SCHOOL OF MEDICINE.—The Infirmary contains 180 beds, a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £47. A tutor's fee of £2 2*s.* is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—Medical Officers: Dr. Keeling, Mr. F. Woolhouse, Mr. R. Favell, and Mr. A. H. Laver. The hospital is devoted to diseases peculiar to women. There is also an obstetric department attached to the hospital for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff of the hospital. Out-patients are attended daily at the hospital. Students can attend the practice of the hospital, and be supplied with cases of midwifery. Secretary, H. B. Warner, Hallamshire-chambers, Church-street.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for nearly 220 patients, including detached fever wards, children's wards, and special ovarian wards. In-patients last year, 1754; out-patients, 8468. The attendance of pupils at this infirmary is duly recognised by all the Examining Boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Dr. J. T. Arlidge, Dr. C. Orton, Messrs. Ashwell and J. G. West. Surgeons: Messrs. W. H. Folker, J. Alcock, and W. D. Spanton. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees &c. may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Founded 1848. Beds, 210. A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at eleven o'clock, and practitioners are welcomed.
